# 1. Introduction

- Encryption process:
  - Alice has a message (**plaintext**) which is **encrypted** using an **encryption key** to produce the **ciphertext**, which is sent to Bob.
  - Bob uses a **decryption key** (which depends on the encryption key) to **decrypt** the ciphertext and recover the original plaintext.
  - It should be computationally infeasible to determine the plaintext without knowing the decryption key.

- **Caesar cipher:**

- Add constant  $k$  to each letter in plaintext to produce ciphertext:

$$\text{ciphertext letter} = \text{plaintext letter} + k \pmod{26}$$

- To decrypt,

$$\text{plaintext letter} = \text{ciphertext letter} - k \pmod{26}$$

- The key is  $k \pmod{26}$ .
- **Note:**  $Z$  is represented as  $0 = 26 \pmod{26}$ ,  $A$  as  $1 \pmod{26}$ .
- Cryptosystem objectives:
  - **Secrecy:** an intercepted message is not able to be decrypted
  - **Integrity:** it is impossible to alter a message without the receiver knowing
  - **Authenticity:** receiver is certain of identity of sender
  - **Non-repudiation:** sender cannot claim they sent a message; the receiver can prove they did.
- **Kerckhoff's principle:** a cryptographic system should be secure even if the details of the system are known to an attacker.
- Types of attack:
  - **Ciphertext-only:** the plaintext is deduced from the ciphertext.
  - **Known-plaintext:** intercepted ciphertext and associated stolen plaintext are used to determine the key.
  - **Chosen-plaintext:** an attacker tricks a sender into encrypting various chosen plaintexts and observes the ciphertext, then uses this information to determine the key.
  - **Chosen-ciphertext:** an attacker tricks the receiver into decrypting various chosen ciphertexts and observes the resulting plaintext, then uses this information to determine the key.

# 2. Symmetric key ciphers

- **Converting letters to numbers:** treat letters as integers modulo 26, with  $A = 1$ ,  $Z = 0 \equiv 26 \pmod{26}$ . Treat string of text as vector of integers modulo 26.
- **Symmetric key cipher:** one in which encryption and decryption keys are equal.
- **Key size:**  $\log_2(\text{number of possible keys})$ .
- Caesar cipher is a **substitution cipher**. A stronger substitution cipher is this: key is permutation of  $\{a, \dots, z\}$ . But vulnerable to plaintext attacks and ciphertext-only

attacks, since different letters (and letter pairs) occur with different frequencies in English.

- **One-time pad:** key is uniformly, independently random sequence of integers mod 26,  $(k_1, k_2, \dots)$ , known to sender and receiver. If message is  $(m_1, m_2, \dots, m_r)$  then ciphertext is  $(c_1, c_2, \dots, c_r) = (k_1 + m_1, k_2 + m_2, \dots, k_r + m_r)$ . To decrypt the ciphertext,  $m_i = c_i - k_i$ . Once  $(k_1, \dots, k_r)$  have been used, they must never be used again.
  - One-time pad is information-theoretically secure against ciphertext-only attack:  $\mathbb{P}(M = m \mid C = c) = \mathbb{P}(M = m)$ .
  - Disadvantage is keys must never be reused, so must be as long as message.
  - Keys must be truly random.
- **Chinese remainder theorem:** let  $m, n \in \mathbb{N}$  coprime,  $a, b \in \mathbb{Z}$ . Then exists unique solution  $x \bmod mn$  to the congruences

$$\begin{aligned} x &\equiv a \pmod{m} \\ x &\equiv b \pmod{n} \end{aligned}$$

- **Block cipher:** group characters in plaintext into blocks of  $n$  (the **block length**) and encrypt each block with a key. So plaintext  $p = (p_1, p_2, \dots)$  is divided into blocks  $P_1, P_2, \dots$  where  $P_1 = (p_1, \dots, p_n)$ ,  $P_2 = (p_{n+1}, \dots, p_{2n})$ , .... Then ciphertext blocks are given by  $C_i = f(\text{key}, P_i)$  for some encryption function  $f$ .
- **Hill cipher:**
  - Plaintext divided into blocks  $P_1, \dots, P_r$  of length  $n$ .
  - Each block represented as vector  $P_i \in (\mathbb{Z}/26\mathbb{Z})^n$
  - Key is invertible  $n \times n$  matrix  $M$  with elements in  $\mathbb{Z}/26\mathbb{Z}$ .
  - Ciphertext for block  $P_i$  is

$$C_i = MP_i$$

It can be decrypted with  $P_i = M^{-1}C_i$ .

- Let  $P = (P_1, \dots, P_r)$ ,  $C = (C_1, \dots, C_r)$ , then  $C = MP$ .
- **Confusion:** each character of ciphertext depends on many characters of key.
- **Diffusion:** each character of ciphertext depends on many characters of plaintext. Ideal diffusion is when changing single character of plaintext changes a proportion of  $(S - 1)/S$  of the characters of the ciphertext, where  $S$  is the number of possible symbols.
- For Hill cipher,  $i$ th character of ciphertext depends on  $i$ th row of key - this is medium confusion. If  $j$ th character of plaintext changes and  $M_{ij} \neq 0$  then  $i$ th character of ciphertext changes.  $M_{ij}$  is non-zero with probability roughly  $25/26$  so good diffusion.
- Hill cipher is susceptible to known plaintext attack:
  - If  $P = (P_1, \dots, P_n)$  are  $n$  blocks of plaintext with length  $n$  such that  $P$  is invertible and we know  $P$  and the corresponding  $C$ , then we can recover  $M$ , since  $C = MP \implies M = CP^{-1}$ .
  - If enough blocks of ciphertext are intercepted, it is very likely that  $n$  of them will produce an invertible matrix  $P$ .

### 3. Public key encryption and RSA

- **Public key cryptosystem:**

- Bob produces encryption key,  $k_E$ , and decryption key,  $k_D$ . He publishes  $k_E$  and keeps  $k_D$  secret.
- To encrypt message  $m$ , Alice sends ciphertext  $c = f(m, k_E)$  to Bob.
- To decrypt ciphertext  $c$ , Bob computes  $g(c, k_D)$ , where  $g$  satisfies

$$g(f(m, k_E), k_D) = m$$

for all messages  $m$  and all possible keys.

- Computing  $m$  from  $f(m, k_E)$  should be hard without knowing  $k_D$ .
- **Converting between messages and numbers:**
- To convert message  $m_1 m_2 \dots m_r$ ,  $m_i \in \{0, \dots, 25\}$  to number, compute

$$m = \sum_{i=1}^r m_i 26^{i-1}$$

- To convert number  $m$  to message, add character  $m \bmod 26$  to message. If  $m < 26$ , stop. Otherwise, floor divide  $m$  by 26 and repeat.
- **Fermat's little theorem:** let  $p$  prime,  $a \in \mathbb{Z}$  coprime to  $p$ , then  $a^{p-1} \equiv 1 \pmod{p}$ .
- **Euler  $\varphi$  function:**

$$\varphi : \mathbb{N} \rightarrow \mathbb{N}, \varphi(n) = |\{1 \leq a \leq n : \gcd(a, n) = 1\}| = |(\mathbb{Z}/n\mathbb{Z})^\times|$$

- $\varphi(p^r) = p^r - p^{r-1}$ ,  $\varphi(mn) = \varphi(m)\varphi(n)$  for  $\gcd(m, n) = 1$ .
- **Euler's theorem:** if  $\gcd(a, n) = 1$ ,  $a^{\varphi(n)} \equiv 1 \pmod{n}$ .
- **RSA algorithm:**
  - $k_E$  is pair  $(n, e)$  where  $n = pq$ , the **RSA modulus**, is product of two distinct primes and  $e \in \mathbb{Z}$ , the **encryption exponent**, is coprime to  $\varphi(n)$ .
  - $k_D$ , the **decryption exponent**, is integer  $d$  such that  $de \equiv 1 \pmod{\varphi(n)}$ .
  - $m$  is an integer modulo  $n$ ,  $m$  and  $n$  are coprime.
  - Encryption:  $c = m^e \pmod{n}$ .
  - Decryption:  $m = c^d \pmod{n}$ .
  - It is recommended that  $n$  have at least 2048 bits. A typical choice of  $e$  is  $2^{16} + 1$ .
- **RSA problem:** given  $n = pq$  a product of two unknown primes,  $e$  and  $m^e \pmod{n}$ , recover  $m$ . If  $n$  can be factored, the RSA is solved.
- **Factorisation problem:** given  $n = pq$  for large distinct primes  $p$  and  $q$ , find  $p$  and  $q$ .
- **RSA signatures:**
  - Public key is  $(n, e)$  and private key is  $d$ .
  - When sending a message  $m$ , message is **signed** by also sending  $s = m^d \bmod n$ , the **signature**.
  - $(m, s)$  is received, **verified** by checking if  $m = s^e \bmod n$ .
  - Forging a signature on a message  $m$  would require finding  $s$  with  $m = s^e \bmod n$ . This is the RSA problem.
  - However, choosing signature  $s$  first then taking  $m = s^e \bmod n$  produces valid pairs.
  - To solve this,  $(m, s)$  is sent where  $s = h(m)^d$ ,  $h$  is **hash function**. Then the message receiver verifies  $h(m) = s^e \bmod n$ .

- Now, for a signature to be forged, an attacker would have to find  $m$  with  $h(m) = s^e \bmod n$ .
- **Hash function** is function  $h : \{\text{messages}\} \rightarrow \mathcal{H}$  that:
  - Can be computed efficiently
  - Is **preimage-resistant**: can't quickly find  $m$  given  $h(m)$ .
  - Is **collision-resistant**: can't quickly find  $m, m'$  such that  $h(m) = h(m')$ .
- **Attacks on RSA**:
  - If you can factor  $n$ , you can compute  $d$ , so can break RSA (as then you know  $\varphi(n)$  so can compute  $e^{-1} \bmod \varphi(n)$ ).
  - If  $\varphi(n)$  is known, then we have  $pq = n$  and  $(p-1)(q-1) = \varphi(n)$  so  $p+q = n - \varphi(n) + 1$ . Hence  $p$  and  $q$  are roots of  $x^2 - (n - \varphi(n) + 1)x + n$ .
  - **Known  $d$  attack**:
    - $de - 1$  is multiple of  $\varphi(n)$  so  $p, q \mid x^{de-1} - 1$ .
    - Look for factor  $K$  of  $de - 1$  with  $x^K - 1$  divisible by  $p$  but not  $q$  (or vice versa) (equivalently,  $(p-1) \mid K$  but  $(q-1) \nmid K$ ).
    - Let  $de - 1 = 2^r s$ ,  $\gcd(2, s) = 1$ , choose random  $x \bmod n$ . Let  $y = x^s$ , then  $y^{2^r} = x^{2^r s} = x^{de-1} \equiv 1 \bmod n$ .
    - If  $y \equiv 1 \bmod n$ , restart with new random  $x$ . Find first occurrence of 1 in  $y, y^2, \dots, y^{2^r} : y^{2^j} \not\equiv 1 \bmod n, y^{2^{j+1}} \equiv 1 \bmod n$  for some  $j \geq 0$ .
    - Let  $a := y^{2^j}$ , then  $a^2 \equiv 1 \bmod n, a \not\equiv 1 \bmod n$ . If  $a \equiv -1 \bmod n$ , restart with new random  $x$ .
    - Now  $n = pq \mid a^2 - 1 = (a+1)(a-1)$  but  $n \nmid (a+1), (a-1)$ . So  $p$  divides one of  $a+1, a-1$  and  $q$  divides the other. So  $\gcd(a-1, n), \gcd(a+1, n)$  are prime factors of  $n$ .
  - **Theorem**: it is no easier to find  $\varphi(n)$  than to factorise  $n$ .
  - **Theorem**: it is no easier to find  $d$  than to factor  $n$ .
  - **Miller-Rabin algorithm** for probabilistic primality testing of  $n$ :
    1. Let  $n-1 = 2^r s$ ,  $\gcd(2, s) = 1$ .
    2. Choose random  $x \bmod n$ , compute  $y = x^s \bmod n$ .
    3. Compute  $y, y^2, \dots, y^{2^r} \bmod n$ .
    4. If 1 isn't in this list,  $n$  is **composite** (with witness  $x$ ).
    5. If 1 is in list preceded by number other than  $\pm 1$ ,  $n$  is **composite** (with witness  $x$ ).
    6. Other,  $n$  is **possible prime** (to base  $x$ ).
  - **Theorem**:
    - If  $n$  prime then it is possible prime to every base.
    - If  $n$  composite then it is possible prime to  $\leq 1/4$  of possible bases.

In particular, if  $k$  random bases are chosen, probability of composite  $n$  being possible prime for all  $k$  bases is  $\leq 4^{-k}$ .

### 3.1. Factorisation

- **Trial division algorithm**: for  $p = 2, 3, 5, \dots$  test whether  $p \mid n$ .
- If  $x^2 \equiv y^2 \bmod n$  but  $x \not\equiv \pm y \bmod n$ , then  $x - y$  is divisible by factor of  $n$  but not by  $n$  itself, so  $\gcd(x - y, n)$  gives proper factor of  $n$  (or 1).
- **Fermat's method**:

- Let  $a = \lceil \sqrt{n} \rceil$ . Compute  $a^2 \bmod n$ ,  $(a+1)^2 \bmod n$  until a square  $x^2 \equiv (a+i)^2 \bmod n$  appears. Then compute  $\gcd(a+i-x, n)$ .
- Works well under special conditions on the factors: if  $|p-q| \leq 2\sqrt{2}\sqrt[4]{n}$  then Fermat's method takes one step:  $x = \lceil \sqrt{n} \rceil$  works.
- **Definition:** an integer is **B-smooth** if all its prime factors are  $\leq B$ .
- **Quadratic sieve:**
  - Choose  $B$  and let  $m$  be number of primes  $\leq B$ .
  - Look at integers  $x = \lceil \sqrt{n} \rceil + k$ ,  $k = 1, 2, \dots$  and check whether  $y = x^2 - n$  is  $B$ -smooth.
  - Once  $y_1 = x_1^2 - n, \dots, y_t = x_t^2 - n$  are all  $B$ -smooth with  $t > m$ , find some product of them that is a square.
  - Deduce a congruence between the squares.
  - Time complexity is  $\exp(\sqrt{\log n \log \log n})$ .

## 4. Diffie-Hellman key exchange

- **Primitive root theorem:** let  $p$  prime, then there exists  $g \in \mathbb{F}_p^\times$  such that  $1, g, \dots, g^{p-2}$  is complete set of residues mod  $p$ .
- Let  $p$  prime,  $g \in \mathbb{F}_p^\times$ . **Order** of  $g$  is smallest  $a \in \mathbb{N}_0$  such that  $g^a = 1$ .  $g$  is **primitive root** if its order is  $p-1$  (equivalently,  $1, g, \dots, g^{p-2}$  is complete set of residues mod  $p$ ).
- Let  $p$  prime,  $g \in \mathbb{F}_p^\times$  primitive root. If  $x \in \mathbb{F}_p^\times$  then  $x = g^L$  for some  $0 \leq L < p-1$ . Then  $L$  is **discrete logarithm** of  $x$  to base  $g$ . Write  $L = L_g(x)$ .
- **Proposition:**
  - $g^{L_g(x)} \equiv x \pmod{p}$  and  $g^a \equiv x \pmod{p} \iff a \equiv L_g(x) \pmod{p-1}$ .
  - $L_g(1) = 0$ ,  $L_g(g) = 1$ .
  - $L_g(xy) \equiv L_g(x) + L_g(y) \pmod{p-1}$ .
  - $L_g(x^{-1}) = -L_g(x) \pmod{p-1}$ .
  - $L_g(g^a \bmod p) \equiv a \pmod{p-1}$ .
  - $h$  is primitive root mod  $p$  iff  $L_g(h)$  coprime to  $p-1$ . So number of primitive roots mod  $p$  is  $\varphi(p-1)$ .
- **Discrete logarithm problem:** given  $p, g, x$ , compute  $L_g(x)$ .
- **Diffie-Hellman key exchange:**
  - Alice and Bob publicly choose prime  $p$  and primitive root  $g \bmod p$ .
  - Alice chooses secret  $\alpha \bmod (p-1)$  and sends  $g^\alpha \bmod p$  to Bob publicly.
  - Bob chooses secret  $\beta \bmod (p-1)$  and sends  $g^\beta \bmod p$  to Alice publicly.
  - Alice and Bob both compute shared secret  $\kappa = g^{\alpha\beta} = (g^\alpha)^\beta = (g^\beta)^\alpha \bmod p$ .
- **Diffie-Hellman problem:** given  $p, g, g^\alpha, g^\beta$ , compute  $g^{\alpha\beta}$ .
- If discrete logarithm problem can be solved, so can Diffie-Hellman problem (since could compute  $\alpha = L_g(g^\alpha)$  or  $\beta = L_g(g^\beta)$ ).
- **Elgamal public key encryption:**
  - Alice chooses prime  $p$ , primitive root  $g$ , private key  $\alpha \bmod (p-1)$ .
  - Her public key is  $y = g^\alpha$ .
  - Bob chooses random  $k \bmod (p-1)$ .
  - To send message  $m$  (integer mod  $p$ ), he sends the pair  $(r, m') = (g^k, my^k)$ .

- To decrypt message, Alice computes  $r^\alpha = g^{\alpha k} = y^k$  and then  $m' r^{-\alpha} = m' y^{-k} = m g^{\alpha k} g^{-\alpha k} m$ .
- If Diffie-Hellman problem is hard, then Elgamal encryption is secure against known plaintext attack.
- Key  $k$  must be random and different each time.
- **Decision Diffie-Hellman problem:** given  $g^a, g^b, c$  in  $\mathbb{F}_p^\times$ , decide whether  $c = g^{ab}$ .
  - This problem is not always hard, as can tell if  $g^{ab}$  is square or not. Can fix this by taking  $g$  to have large prime order  $q \mid (p-1)$ .  $p = 2q + 1$  is a good choice.
- **Elgamal signatures:**
  - Public key is  $(p, g)$ ,  $y = g^\alpha$  for private key  $\alpha$ .
  - **Valid Elgamal signature** on  $m \in \{0, \dots, p-2\}$  is pair  $(r, s)$ ,  $0 \leq r, s \leq p-1$  such that

$$y^r r^s = g^m \pmod{p}$$

- Alice computes  $r = g^k$ ,  $k \in (\mathbb{Z}/(p-1))^\times$  random.  $k$  should be different each time.
- Then  $g^{\alpha r} g^{ks} \equiv g^m \pmod{p}$  so  $\alpha r + ks \equiv m \pmod{p-1}$  so  $s = k^{-1}(m - \alpha r) \pmod{p-1}$ .
- **Elgamal signature problem:** given  $p, g, y, m$ , find  $r, s$  such that  $y^r r^s = m$ .
- **Discrete logarithm problem:** given prime  $p$ , primitive root  $g \pmod{p}$ ,  $x \in \mathbb{F}_p^\times$ , calculate  $L_g(x)$ .
- **Baby-step giant-step algorithm** for solving DLP:
  - Let  $N = \lceil \sqrt{p-1} \rceil$ .
  - Baby-steps: compute  $g^j \pmod{p}$  for  $0 \leq j < N$ .
  - Giant-steps: compute  $x g^{-Nk} \pmod{p}$  for  $0 \leq k < N$ .
  - Look for a match between baby-steps and giant-steps lists:  $g^j = x g^{-Nk} \implies x = g^{j+Nk}$ .
  - Always works since if  $x = g^L$  for  $0 \leq L < p-1 \leq N^2$ ,  $L$  can be written as  $j + Nk$  with  $j, k \in \{0, \dots, N-1\}$ .
- **Index calculus** method for solving DLP  $x = g^L$ :
  - Fix smoothness bound  $B$ .
  - Find many multiplicative relations between  $B$ -smooth numbers and powers of  $g \pmod{p}$ .
  - Solve these relations to find discrete logarithms of primes  $\leq B$ .
  - For  $i = 1, 2, \dots$  compute  $x g^i \pmod{p}$  until one is  $B$ -smooth, then use result from previous step.
- **Pohlig-Hellman algorithm** computes discrete logarithms  $\pmod{p}$  with approximate complexity  $\log(p)\sqrt{\ell}$  where  $\ell$  is largest prime factor of  $p-1$ , so is fast if  $p-1$  is  $B$ -smooth. Therefore  $p$  is chosen so that  $p-1$  has large prime factor, e.g. choose **Germain prime**  $p = 2q + 1$ , with  $q$  prime.

## 5. Elliptic curves

- **Definition: abelian group**  $(G, \circ)$  satisfies:
  - **Associativity:**  $\forall a, b, c \in G, a \circ (b \circ c) = (a \circ b) \circ c$ .
  - **Identity:**  $\exists e \in G : \forall g \in G, e \circ g = g$ .

- **Inverses:**  $\forall g \in G, \exists h \in G : g \circ h = h \circ g = e$
- **Commutativity:**  $\forall a, b \in G, a \circ b = b \circ a$ .
- **Definition:**  $H \subseteq G$  is **subgroup** of  $G$  if  $(H, \circ)$  is group.
- To show  $H$  is subgroup, sufficient to show  $g, h \in H \Rightarrow g \circ h \in H$  and  $h^{-1} \in H$ .
- **Notation:** for  $g \in G$ , write  $[n]g$  for  $g \circ \dots \circ g$   $n$  times if  $n > 0$ ,  $e$  if  $n = 0$ ,  $[-n]g^{-1}$  if  $n < 0$ .
- **Definition:** subgroup generated by  $g$  is

$$\langle g \rangle = \{[n]g : n \in \mathbb{Z}\}$$

If  $\langle g \rangle$  finite, it has **order**  $n$ , and  $g$  has **order**  $n$ . If  $G = \langle g \rangle$  for some  $g \in G$ ,  $G$  is **cyclic** and  $g$  is **generator**.

- **Lagrange's theorem:** let  $G$  finite group,  $H$  subgroup of  $G$ , then  $|H| \mid |G|$ .
- **Corollary:** if  $G$  finite,  $g \in G$  has order  $n$ , then  $n \mid |G|$ .
- **DLP for abelian groups:** given  $G$  a cyclic abelian group,  $g \in G$  a generator of  $G$ ,  $x \in G$ , find  $L$  such that  $[L]g = x$ .  $L$  is well-defined modulo  $|G|$ .
- **Definition:** let  $(G, \circ)$ ,  $(H, \bullet)$  abelian groups, **homomorphism** between  $G$  and  $H$  is  $f : G \rightarrow H$  with

$$\forall g, g' \in G, \quad f(g \circ g') = f(g) \bullet f(g')$$

**Isomorphism** is bijective homomorphism.  $G$  and  $H$  are **isomorphic**,  $G \cong H$ , if there is isomorphism between them.

- **Fundamental theorem of finite abelian groups:** let  $G$  finite abelian group, then there exist unique integers  $2 \leq n_1, \dots, n_r$  with  $n_i \mid n_{i+1}$  for all  $i$ , such that

$$G \simeq (\mathbb{Z}/n_1) \times \dots \times (\mathbb{Z}/n_r)$$

In particular,  $G$  is isomorphic to product of cyclic groups.

- **Definition:** let  $K$  field,  $\text{char}(K) > 3$ . An **elliptic curve** over  $K$  is defined by the equation

$$y^2 = x^3 + ax + b$$

where  $a, b \in K$ ,  $\Delta_E := 4a^3 + 27b^2 \neq 0$ .

- **Remark:**  $\Delta_E \neq 0$  is equivalent to  $x^3 + ax + b$  having no repeated roots (i.e.  $E$  is smooth).
- **Definition:** for elliptic curve  $E$  defined over  $K$ , a  **$K$ -point (point)** on  $E$  is either:
  - A **normal point:**  $(x, y) \in K^2$  satisfying the equation defining  $E$ .
  - The **point at infinity**  $\overline{O}$  which can be thought of as infinitely far along the  $y$ -axis (in either direction).

Denote set of all  $K$ -points on  $E$  as  $E(K)$ .

- Any elliptic curve  $E(K)$  is an abelian group, with group operation  $\oplus$  is defined as:
  - We should have  $P \oplus Q \oplus R = \overline{O}$  iff  $P, Q, R$  lie on straight line.
  - In this case,  $P \oplus Q = -R$ .
  - To find line  $\ell$  passing through  $P = (x_0, y_0)$  and  $Q = (x_1, y_1)$ :
    - If  $x_0 \neq x_1$ , then equation of  $\ell$  is  $y = \lambda x + \mu$ , where

$$\lambda = \frac{y_1 - y_0}{x_1 - x_0}, \quad \mu = y_0 - \lambda x_0$$

Now

$$\begin{aligned} y^2 &= x^3 + ax + b = (\lambda x + \mu)^2 \\ \implies 0 &= x^3 - \lambda^2 x^2 + (a - 2\lambda\mu)x + (b - \mu^2) \end{aligned}$$

Since sum of roots of monic polynomial is equal to minus the coefficient of the second highest power, and two roots are  $x_0$  and  $x_1$ , the third root is  $x_2 = \lambda^2 - x_0 - x_1$ . Then  $y_2 = \lambda x_2 + \mu$  and  $R = (x_2, y_2)$ .

- If  $x_0 = x_1$ , then using implicit differentiation:

$$\begin{aligned} y^2 &= x^3 + ax + b \\ \implies \frac{dy}{dx} &= \frac{3x^2 + a}{2y} \end{aligned}$$

and the rest is as above, but instead with  $\lambda = \frac{3x_0^2 + a}{2y_0}$ .

- **Definition: group law** of elliptic curves: let  $E : y^2 = x^3 + ax + b$ . For all normal points  $P = (x_0, y_0), Q = (x_1, y_1) \in E(K)$ , define
  - $\bar{O}$  is group identity:  $P \oplus \bar{O} = \bar{O} \oplus P = P$ .
  - If  $P = -Q = (x_0, -y_0)$ ,  $P \oplus Q = \bar{O}$ .
  - Otherwise,  $P \oplus Q = (x_2, -y_2)$ , where

$$\begin{aligned} x_2 &= \lambda^2 - (x_0 + x_1), \\ y_2 &= \lambda x_2 + \mu, \\ \lambda &= \begin{cases} \frac{y_1 - y_0}{x_1 - x_0} & \text{if } x_0 \neq x_1 \\ \frac{3x_0^2 + a}{2y_0} & \text{if } x_0 = x_1 \end{cases}, \\ \mu &= y_0 - \lambda x_0 \end{aligned}$$

- **Example:**
  - Let  $E$  be given by  $y^2 = x^3 + 17$  over  $\mathbb{Q}$ ,  $P = (-1, 4) \in E(\mathbb{Q})$ ,  $Q = (2, 5) \in E(\mathbb{Q})$ . To find  $P \oplus Q$ ,

$$\lambda = \frac{5 - 4}{2 - (-1)} = \frac{1}{3}, \quad \mu = 4 - \lambda(-1) = \frac{13}{3}$$

So  $x_2 = \lambda^2 - (-1) - 2 = -\frac{8}{9}$  and  $y_2 = -(\lambda x_2 + \mu) = -\frac{109}{27}$  hence

$$P \oplus Q = \left( -\frac{8}{9}, -\frac{109}{27} \right)$$

To find  $[2]P$ ,

$$\lambda = \frac{3(-1)^2 + 0}{2 \cdot 4} = \frac{3}{8}, \quad \mu = 4 - \frac{3}{8} \cdot (-1) = \frac{35}{8}$$

so  $x_3 = \lambda^2 - 2 \cdot (-1) \frac{137}{64}$ ,  $y_3 = -(\lambda x_3 + \mu) = -\frac{2651}{512}$  hence

$$[2]P = (x_3, y_3) = \left( \frac{137}{64}, -\frac{2651}{512} \right)$$

- **Hasse's theorem:** let  $|E(\mathbb{F}_p)| = N$ , then

$$|N - (p + 1)| \leq 2\sqrt{p}$$

- **Theorem:**  $E(\mathbb{F}_p)$  is isomorphic to either  $\mathbb{Z}/k$  or  $\mathbb{Z}/m \times \mathbb{Z}/n$  with  $m \mid n$ .
- **Elliptic curve Diffie-Hellman:**
  - Alice and Bob publicly choose elliptic curve  $E(\mathbb{F}_p)$  and  $P \in \mathbb{F}_p$  with order a large prime  $n$ .
  - Alice chooses random  $\alpha \in \{0, \dots, n-1\}$  and publishes  $Q_A = [\alpha]P$ .
  - Bob chooses random  $\beta \in \{0, \dots, n-1\}$  and publishes  $Q_B = [\beta]P$ .
  - Alice computes  $[\alpha]Q_B = [\alpha\beta]P$ , Bob computes  $[\beta]Q_A = [\beta\alpha]P$ .
  - Shared key is  $K = [\alpha\beta]P$ .
- **Elliptic curve Elgamal signatures:**
  - Use agreed elliptic curve  $E$  over  $\mathbb{F}_p$ , point  $P \in E(\mathbb{F}_p)$  of prime order  $n$ .
  - Alice wants to sign message  $m$ , encoded as integer mod  $n$ .
  - Alice generates private key  $\alpha \in \mathbb{Z}/n$  and public key  $Q = [\alpha]P$ .
  - Valid signature is  $(R, s)$  where  $R = (x_R, y_R) \in E(\mathbb{F}_p)$ ,  $s \in \mathbb{Z}/n$ ,  $[\tilde{x}_R]Q \oplus [s]R = [m]P$ .
  - To generate a valid signature, Alice chooses random  $0 \neq k \in \mathbb{Z}/n$  and sets  $R = [k]P$ ,  $s = k^{-1}(m - \tilde{x}_R \alpha)$ .
  - $k$  must be randomly generated for each message.
- **Baby-step giant-step algorithm for elliptic curve DLP:** given  $P$  and  $Q = [\alpha]P$ , find  $\alpha$ :
  - Let  $N = \lceil \sqrt{n} \rceil$ ,  $n$  is order of  $P$ .
  - Compute  $P, [2]P, \dots, [N-1]P$ .
  - Compute  $Q \oplus [-N]P, Q \oplus [-2N]P, \dots, Q \oplus [-(N-1)N]P$  and find a match between these two lists:  $[i]P = Q \oplus [-jN]P$ , then  $[i + jN]P = Q$  so  $\alpha = i + jN$ .
- For well-chosen elliptic curves, the best algorithm for solving DLP is the baby-step giant-step algorithm, with run time  $O(\sqrt{n}) \approx O(\sqrt{p})$ . This is much slower than the index-calculus method for the DLP in  $\mathbb{F}_p^\times$ .
- **Pollard's  $p-1$  algorithm** to factorise  $n = pq$ :
  - Choose smoothness bound  $B$ .
  - Choose random  $2 \leq a \leq n-2$ . Set  $a_1 = a$ ,  $i = 1$ .
  - Compute  $a_i = a_{i-1}^i \bmod n$ . Find  $d = \gcd(a_i - 1, n)$ . If  $1 < d < n$ , we have found a nontrivial factor of  $n$ . If  $d = n$ , pick new  $a$  and retry. If  $d = 1$ , increment  $i$  by 1 and repeat this step.
  - A variant is instead of computing  $a_i = a_{i-1}^i$ , compute  $a_i = a_{i-1}^{m_{i-1}}$  where  $m_1, \dots, m_r$  are the prime powers  $\leq B$  (each prime power is the maximal prime power  $\leq B$  for that prime).
  - The algorithm works if  $p-1$  is  **$B$ -powersmooth** (all prime power factors are  $\leq B$ ), since if  $b$  is order of  $a \bmod p$ , then  $b \mid (p-1)$  so  $b \mid B!$  (also  $b \mid m_1 \cdots m_r$ ).

If the first  $i$  for which  $i!$  (or  $m_1 \cdots m_i$ ) is divisible by  $d$  and order of  $a \bmod q$ , then  $a_i - 1 = a^{i!} - 1 \bmod n$  is divisible by both  $p$  and  $q$ , so must retry with different  $a$ .

- Let  $n = pq$ ,  $p, q$  prime,  $a, b \in \mathbb{Z}$ ,  $\gcd(4a^3 + 27b^2, n) = 1$ . Then  $E : y^2 = x^3 + ax + b$  defines elliptic curve over  $\mathbb{F}_p$  and over  $\mathbb{F}_q$ . If  $(x, y) \in \mathbb{Z}/n$  is solution to  $E \bmod n$  then can reduce coordinates  $\bmod p$  to obtain non-infinite point of  $E(\mathbb{F}_p)$  and  $\bmod q$  to obtain non-infinite point of  $E(\mathbb{F}_q)$ .
- **Proposition:** let  $P_1, P_2 \in E \bmod n$ , with

$$(P_1 \bmod p) \oplus (P_2 \bmod p) = \overline{O}$$

$$(P_1 \bmod q) \oplus (P_2 \bmod q) \neq \overline{O}$$

Then  $\gcd(x_1 - x_2, n)$  (or  $\gcd(2x_1, n)$  if  $P_1 = P_2$ ) is factor of  $n$ .

- **Lenstra's algorithm** to factorise  $n$ :
  - Choose smoothness bound  $B$ .
  - Choose random elliptic curve  $E$  over  $\mathbb{Z}/n$  with  $\gcd(\Delta_E, n) = 1$  and  $P = (x, y)$  a point on  $E$ .
  - Set  $P_1 = P$ , attempt to compute  $P_i$ ,  $2 \leq i \leq B$  by  $P_i = [i]P_{i-1}$ . If one of these fails, a divisor of  $n$  has been found (by failing to compute an inverse  $\bmod n$ ). If this divisor is trivial, restart with new curve and point.
  - If  $i = B$  is reached, restart with new curve and point.
  - Again, a variant is calculating  $P_i = [m_i]P_{i-1}$  instead of  $[i]P_{i-1}$  where  $m_1, \dots, m_r$  are the prime powers  $\leq B$
- Lenstra's algorithm works if  $|E(\mathbb{Z}/p)|$  is  $B$ -powersmooth but  $|E(\mathbb{Z}/q)|$  isn't. Since we can vary  $E$ , it is very likely to work eventually.
- Running time depends on  $p$  (the smaller prime factor):

$$O\left(\exp\left(\sqrt{2 \log(p) \log \log(p)}\right)\right)$$

Compare this to the general number field sieve running time:

$$O\left(\exp\left(C(\log n)^{1/3}(\log \log n)^{2/3}\right)\right)$$

## 5.1. Torsion points

- **Definition:** let  $G$  abelian group.  $g \in G$  is a **torsion** if it has finite order. If order divides  $n$ , then  $[n]g = e$  and  $g$  is  **$n$ -torsion**.
- **Definition:**  **$n$ -torsion subgroup** is

$$G[n] := \{g \in G : [n]g = e\}$$

- **Definition:** **torsion subgroup** of  $G$  is

$$G_{\text{tors}} = \{g \in G : g \text{ is torsion}\} = \bigcup_{n \in \mathbb{N}} G[n]$$

- **Example:**
  - In  $\mathbb{Z}$ , only 0 is torsion.
  - In  $(\mathbb{Z}/10)^\times$ , by Lagrange's theorem, every point is 4-torsion.
  - For finite groups  $G$ ,  $G_{\text{tors}} = G = G[|G|]$  by Lagrange's theorem.

## 5.2. Rational points

- **Note:** for elliptic curve  $E : y^2 = x^3 + ax + b$  over  $\mathbb{Q}$ , can assume that  $a, b \in \mathbb{Z}$ .
- **Nagell-Lutz theorem:** let  $E$  elliptic curve, let  $P = (x, y) \in E(\mathbb{Q})_{\text{tors}}$ . Then  $x, y \in \mathbb{Z}$ , and either  $y = 0$  (in which case  $P$  is 2-torsion) or  $y^2 \mid \Delta_E$ .
- **Corollary:**  $E(\mathbb{Q})_{\text{tors}}$  is finite.
- **Example:** can use Nagell-Lutz to show a point is not torsion.
  - $P = (0, 1)$  lies on elliptic curve  $y^2 = x^3 - x + 1$ .  $[2]P = (\frac{1}{4}, -\frac{7}{8}) \notin \mathbb{Z}^2$ . Then  $[2]P$  is not torsion, hence  $P$  is not torsion. So  $E(\mathbb{Q})$  contains distinct points  $\dots, [-2]P, -P, \bar{O}, P, [2]P, \dots$ , hence  $E$  has infinitely many solutions in  $\mathbb{Q}$ .
- **Mazur's theorem:** let  $E$  be elliptic curve over  $\mathbb{Q}$ . Then  $E(\mathbb{Q})_{\text{tors}}$  is either:
  - cyclic of order  $1 \leq N \leq 10$  or order 12, or
  - of the form  $\mathbb{Z}/2 \times \mathbb{Z}/2N$  for  $1 \leq N \leq 4$ .
- **Definition:** let  $E : y^2 = x^3 + ax + b$  defined over  $\mathbb{Q}$ ,  $a, b \in \mathbb{Z}$ . For odd prime  $p$ , taking reductions  $\bar{a}, \bar{b} \bmod p$  gives curve over  $\mathbb{F}_p$ :

$$\bar{E} : y^2 = x^3 + \bar{a}x + \bar{b}$$

This is elliptic curve if  $\Delta_E \not\equiv 0 \bmod p$ , in which case  $p$  is **prime of good reduction** for  $E$ .

- **Theorem:** let  $E : y^2 = x^3 + ax + b$  defined over  $\mathbb{Q}$ ,  $a, b \in \mathbb{Z}$ ,  $p$  be odd prime of good reduction for  $E$ . Then  $f : E(\mathbb{Q})_{\text{tors}} \rightarrow \bar{E}(\mathbb{F}_p)$  defined by

$$f(x, y) := (\bar{x}, \bar{y}), \quad f(\bar{O}) := \bar{O}$$

is injective (note  $x, y \in \mathbb{Z}$  by Nagell-Lutz).

- So  $E(\mathbb{Q})_{\text{tors}}$  can be thought of as subgroup of  $E(\mathbb{F}_p)$  for any prime  $p$  of good reduction, so by Lagrange's theorem,  $|E(\mathbb{Q})_{\text{tors}}|$  divides  $|E(\mathbb{F}_p)|$ .
- **Mordell's theorem:** if  $E$  is elliptic curve over  $\mathbb{Q}$ , then

$$E(\mathbb{Q}) \cong E(\mathbb{Q})_{\text{tors}} \times \mathbb{Z}^r$$

for some  $r \geq 0$  the **rank** of  $E$ . So for some  $P_1, \dots, P_r \in E(\mathbb{Q})$ ,

$$E(\mathbb{Q}) = \{n_1 P_1 + \dots + n_r P_r + T : n_i \in \mathbb{Z}, T \in E(\mathbb{Q})_{\text{tors}}\}$$

$P_1, \dots, P_r, T$  are **generators** for  $E(\mathbb{Q})$ .

## 6. Basic coding theory

### 6.1. First definitions

- **Definition:**
  - **Alphabet**  $A$  is finite set of symbols.
  - $A^n$  is set of all lists of  $n$  symbols from  $A$  - these are **words of length  $n$** .
  - **Code of block length  $n$  on  $A$**  is subset of  $A^n$ .
  - **Codeword** is element of a code.

Definition[ If  $|A| = 2$ , codes on  $A$  are **binary** codes. If  $|A| = 3$ , codes on  $A$  are **ternary codes**. If  $|A| = q$ , codes on  $A$  are  **$q$ -ary** codes. Generally, use  $A = \{0, 1, \dots, q-1\}$ . ]

**Definition.** Let  $x = x_1 \dots x_n, y = y_1 \dots y_n \in A^n$ . **Hamming distance** between  $x$  and  $y$  is number of indices where  $x$  and  $y$  differ:

$$d : A^n \times A^n \rightarrow \{0, \dots, n\}, \quad d(x, y) := |\{i \in [n] : x_i \neq y_i\}|$$

So  $d(x, y)$  is minimum number of changes needed to change  $x$  to  $y$ . If  $x$  transmitted and  $y$  received, then  $d(x, y)$  **symbol-errors** have occurred.

**Proposition.** Let  $x, y$  words of length  $n$ .

- $0 \leq d(x, y) \leq n$ .
- $d(x, y) = 0 \iff x = y$ .
- $d(x, y) = d(y, x)$ .
- $\forall z \in A^n, d(x, y) \leq d(x, z) + d(z, y)$ .

**Definition.** **Minimum distance** of code  $C$  is

$$d(C) := \min\{d(x, y) : x, y \in C, x \neq y\} \in \mathbb{N}$$

**Notation.** Code of block length  $n$  with  $M$  codewords and minimum distance  $d$  is called  $(n, M, d)$  (or  $(n, M)$ ) code. A  $q$ -ary code is called an  $(n, M, d)_q$  code.

**Definition.** Let  $C \subseteq A^n$  code,  $x$  word of length  $n$ . A **nearest neighbour** of  $x$  is codeword  $c \in C$  such that  $d(x, c) = \min\{d(x, y) : y \in C\}$ .

## 6.2. Nearest-neighbour decoding

**Definition.** **Nearest-neighbour decoding (NND)** means if word  $x$  received, it is decoded to a nearest neighbour of  $x$  in a code  $C$ .

**Proposition.** Let  $C$  be code with minimum distance  $d$ , let word  $x$  be received with  $t$  symbol errors. Then

- If  $t \leq d - 1$ , then we can detect that  $x$  has some errors.
- If  $t \leq \lfloor \frac{d-1}{2} \rfloor$ , then NND will correct the errors.

## 6.3. Probabilities

**Definition.**  **$q$ -ary symmetric channel with symbol-error probability  $p$**  is channel for  $q$ -ary alphabet  $A$  such that:

- For every  $a \in A$ , probability that  $a$  is changed in channel is  $p$ .
- For every  $a \neq b \in A$ , probability that  $a$  is changed to  $b$  in channel is

$$\mathbb{P}(b \text{ received} \mid a \text{ sent}) = \frac{p}{q-1}$$

i.e. symbol-errors in different positions are independent events.

**Proposition.** Let  $c$  codeword in  $q$ -ary code  $C \subseteq A^n$  sent over  $q$ -ary symmetric channel with symbol-error probability  $p$ . Then

$$\mathbb{P}(x \text{ received} \mid c \text{ sent}) = \left( \frac{p}{q-1} \right)^t (1-p)^{n-t}, \quad \text{where } t = d(c, x)$$

**Example.** Let  $C = \{000, 111\} \subset \{0, 1\}^3$ .

$x$	$t = d(000, x)$	chance 000 received as $x$	chance if $p = 0.01$	NND decodes correctly?
000	0	$(1-p)^3$	0.970299	yes
100	1	$p(1-p)^2$	0.009801	yes
010	1	$p(1-p)^2$	0.009801	yes
001	1	$p(1-p)^2$	0.009801	yes
110	2	$p^2(1-p)$	0.000099	no
101	2	$p^2(1-p)$	0.000099	no
011	2	$p^2(1-p)$	0.000099	no
111	3	$p^3$	0.000001	no

**Corollary.** If  $p < \frac{q-1}{q}$  then  $P(x \text{ received} \mid c \text{ sent})$  increases as  $d(x, c)$  decreases.

**Remark.** By Bayes' theorem,

$$\mathbb{P}(c \text{ sent} \mid x \text{ received}) = \frac{\mathbb{P}(c \text{ sent and } x \text{ received})}{\mathbb{P}(x \text{ received})} = \frac{\mathbb{P}(c \text{ sent})\mathbb{P}(x \text{ received} \mid c \text{ sent})}{\mathbb{P}(x \text{ received})}$$

**Proposition.** Let  $C$  be  $q$ -ary  $(n, M, d)$  code used over  $q$ -ary symmetric channel with symbol-error probability  $p < (q-1)/q$ , and each codeword  $c \in C$  is equally likely to be sent. Then for any word  $x$ ,  $\mathbb{P}(c \text{ sent} \mid x \text{ received})$  increases as  $d(x, c)$  decreases.

## 6.4. Bounds on codes

- **Proposition (singleton bound):** for  $q$ -ary code  $(n, M, d)$  code,  $M \leq q^{n-d+1}$ .

**Definition.** Code which saturates singleton bound is called **maximum distance separable (MDS)**.

**Example.** Let  $C_n$  be **binary repetition code** of block length  $n$ ,

$$C_n := \{\underbrace{00\dots 0}_n, \underbrace{11\dots 1}_n\} \subset \{0, 1\}^n$$

$C_n$  is  $(n, 2, n)_2$  code, and  $2 = 2^{n-n+1}$  so  $C_n$  is MDS code.

**Definition.** Let  $A$  be alphabet,  $|A| = q$ . Let  $n \in \mathbb{N}$ ,  $0 \leq t \leq n$ ,  $t \in \mathbb{N}$ ,  $x \in A^n$ .

- **Ball of radius  $t$  around  $x$**  is

$$S(x, t) := \{y \in A^n : d(y, x) \leq t\}$$

- Code  $C \subseteq A^n$  is **perfect** if

$$\exists t \in \mathbb{N} : A^n = \coprod_{c \in C} S(c, t)$$

where  $\coprod$  is disjoint union.

**Example.** For  $C = \{000, 111\} \subset \{0, 1\}^3$ ,  $S(000, 1) = \{000, 100, 010, 001\}$  and  $S(111, 1) = \{111, 011, 101, 110\}$ . These are disjoint and  $S(000, 1) \cup S(111, 1) = \{0, 1\}^3$ , so  $C$  is perfect.

**Example.** Let  $C = \{111, 020, 202\} \subset \{0, 1, 2\}^3$ .  $\forall c \in C, d(c, 012) = 2$ . So 012 is not in any  $S(c, 1)$  but is in every  $S(c, 2)$ , so  $C$  is not perfect.

**Lemma.** Let  $|A| = q, x \in \mathbb{A}^n$ , then

$$|S(x, t)| = \sum_{k=0}^t \binom{n}{k} (q-1)^k$$

**Example.** Let  $C = \{111, 020, 202\} \subset \{0, 1, 2\}^3$ , so  $q = 3, n = 3$ . So  $|S(x, 1)| = \binom{3}{0} + \binom{3}{1}(3-1) = 7$ ,  $|S(x, 2)| = \binom{3}{0} + \binom{3}{1}(3-1) + \binom{3}{2}(3-1)^2 = 19$ . But  $|\{0, 1, 2\}|^3 = 27$  and  $7 \nmid 27, 19 \nmid 27$ , so  $\{0, 1, 2\}^3$  can't be partitioned by balls of either size. So  $C$  can't be perfect.  $|S(x, 3)| = 27$ , but then  $C$  must contain only one codeword to be perfect, and  $|S(x, 0)| = 1$ , but then  $C = \mathbb{A}^n$  to be perfect. These are trivial, useless codes.

• **Proposition (Hamming/sphere-packing bound):**  $q$ -ary  $(n, M, d)$  code satisfies

$$M \sum_{k=0}^t \binom{n}{k} (q-1)^k \leq q^n, \quad \text{where } t = \left\lfloor \frac{d-1}{2} \right\rfloor$$

**Corollary.** Code saturates Hamming bound iff it is perfect.

## 7. Linear codes

### 7.1. Finite vector spaces

**Definition.** **Linear code** of block length  $n$  is subspace of  $\mathbb{F}_q^n$ .

**Example.** Let  $\mathbf{x} = (0, 1, 2, 0), \mathbf{y} = (1, 1, 1, 1), \mathbf{z} = (0, 2, 1, 0) \in \mathbb{F}_3^4$ .  $C_1 = \{\mathbf{x}, \mathbf{y}, \mathbf{0}\}$  is not linear code since e.g.  $\mathbf{x} + \mathbf{y} = (1, 2, 0, 1) \notin C_1$ .  $C_2 = \{\mathbf{x}, \mathbf{z}, \mathbf{0}\}$  is linear code.

**Notation.** Spanning set of  $S$  is  $\langle S \rangle$ .

**Proposition.** If linear code  $C \subseteq \mathbb{F}_q^n$  has  $\dim(C) = k$ , then  $|C| = q^k$ .

**Definition.** A  $q$ -ary  $[n, k, d]$  code is linear code: a subspace of  $\mathbb{F}_q^n$  of dimension  $k$  with minimum distance  $d$ . Note: a  $q$ -ary  $[n, k, d]$  code is a  $q$ -ary  $(n, q^k, d)$  code.

### 7.2. Weight and minimum distance

**Definition.** **Weight** of  $\mathbf{x} \in \mathbb{F}_q^n$ ,  $w(\mathbf{x})$ , is number of non-zero entries in  $\mathbf{x}$ :

$$w(\mathbf{x}) = |\{i \in [n] : x_i \neq 0\}|$$

**Lemma.**  $\forall \mathbf{x}, \mathbf{y} \in \mathbb{F}_q^n, d(\mathbf{x}, \mathbf{y}) = w(\mathbf{x} - \mathbf{y})$ . In particular,  $w(\mathbf{x}) = d(\mathbf{x}, \mathbf{0})$ .

**Proposition.** Let  $C \subseteq \mathbb{F}_q^n$  linear code, then

$$d(C) = \min\{w(\mathbf{c}) : \mathbf{c} \in C, \mathbf{c} \neq \mathbf{0}\}$$

**Remark.** To find  $d(C)$  for linear code with  $q^k$  words, only need to consider  $q^k$  weights instead of  $\binom{q^k}{2}$  distances.

## 8. Codes as images

## 8.1. Generator-matrices

**Definition.** Let  $C \subseteq \mathbb{F}_q^n$  be linear code. Let  $G \in M_{k,n}(\mathbb{F}_q)$ ,  $f_G : \mathbb{F}_q^k \rightarrow \mathbb{F}_q^n$  be linear map defined by  $f_G(\mathbf{x}) = \mathbf{x}G$ . Then  $G$  is **generator-matrix** for  $C$  if

- $C = \text{im}(f) = \{\mathbf{x}G : \mathbf{x} \in \mathbb{F}_q^k\} \subseteq \mathbb{F}_q^n$ .
- The rows of  $G$  are linearly independent.

i.e.  $G$  is generator-matrix for  $C$  iff rows of  $G$  form basis for  $C$  (note  $\mathbf{x}G = x_1\mathbf{g}_1 + \dots + x_k\mathbf{g}_k$  where  $\mathbf{g}_i$  are rows of  $G$ ).

**Remark.** Given linear code  $C = \langle \mathbf{a}_1, \dots, \mathbf{a}_m \rangle$ , a generator-matrix can be found for  $C$  by constructing the matrix  $A$  with rows  $\mathbf{a}_i$ , then performing elementary row operations to bring  $A$  into RREF. Once the  $m - k$  bottom zero rows have been removed, the resulting matrix is a generator-matrix.

**Example.** Let  $C = \langle (0, 0, 3, 1, 4), (2, 4, 1, 4, 0), (5, 3, 0, 1, 6) \rangle \subseteq \mathbb{F}_7^5$ .

$$A = \begin{bmatrix} 2 & 4 & 1 & 4 & 0 \\ 5 & 3 & 0 & 1 & 6 \\ 0 & 0 & 3 & 1 & 4 \end{bmatrix} \xrightarrow{A_{12}(1)} \begin{bmatrix} 2 & 4 & 1 & 4 & 0 \\ 0 & 0 & 1 & 5 & 6 \\ 0 & 0 & 3 & 1 & 4 \end{bmatrix} \xrightarrow{M_1(4)} \begin{bmatrix} 1 & 2 & 4 & 2 & 0 \\ 0 & 0 & 1 & 5 & 6 \\ 0 & 0 & 3 & 1 & 4 \end{bmatrix} \xrightarrow{A_{21}(3), A_{23}(4)} \begin{bmatrix} 1 & 2 & 0 & 3 & 4 \\ 0 & 0 & 1 & 5 & 6 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

So  $G = \begin{bmatrix} 1 & 2 & 0 & 3 & 4 \\ 0 & 0 & 1 & 5 & 6 \end{bmatrix}$  is generator matrix for  $C$  and  $\dim(C) = 2$ .

## 8.2. Encoding and channel decoding

## 8.3. Equivalence and standard form

**Definition.** Codes  $C_1, C_2$  of block length  $n$  over alphabet  $A$  are **equivalent** if we can transform one to the other by applying sequence of the following two kinds of changes to all the codewords (simultaneously):

- Permute the  $n$  positions.
- In a particular position, permuting the  $|A| = q$  symbols.

**Proposition.** Equivalent codes have the same parameters  $(n, M, d)$ .

**Definition.** Linear codes  $C_1, C_2 \subseteq \mathbb{F}_q^n$  are **monomially equivalent** if we can obtain one from the other by applying sequence of the following two kinds of changes to all codewords (simultaneously):

- Permuting the  $n$  positions.
- In particular position, multiply by  $\lambda \in \mathbb{F}_q^\times$ .

If only the first change is used, the codes are **permutation equivalent**.

**Definition.**  $P \in M_n(\mathbb{F}_q)$  is **permutation matrix** if it has a single 1 in each row and column, and zeros elsewhere. Any permutation of  $n$  positions of row vector in  $\mathbb{F}_q^n$  can be described as right multiplication by permutation matrix.

**Proposition.** Permutation matrices are orthogonal:  $P^T = P^{-1}$ .

**Proposition.** Let  $C_1, C_2 \subseteq \mathbb{F}_q^n$  linear codes with generator matrices  $G_1, G_2$ . Then if  $G_1 = G_2P$  for permutation matrix  $P$ , then  $C_1$  and  $C_2$  are permutation equivalent.

**Definition.**  $M \in M_m(\mathbb{F}_q)$  is **monomial matrix** if it has exactly one non-zero element in each row and column.

**Proposition.** Monomial matrix  $M$  can always be written as  $M = DP$  or  $M = PD'$  where  $P$  is permutation matrix and  $D, D'$  are diagonal matrices.  $P$  is **permutation part**,  $D$  and  $D'$  are **diagonal parts** of  $M$ .

**Example.**

$$\begin{bmatrix} 0 & 2 & 0 \\ 0 & 0 & 3 \\ 1 & 0 & 0 \end{bmatrix} = \begin{bmatrix} 2 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix} = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 3 \end{bmatrix}$$

**Proposition.** Let  $C_1, C_2 \subseteq \mathbb{F}_q^n$  be linear codes with generator-matrices  $G_1, G_2$ . Then if  $G_2 = G_1 M$  for some monomial matrix  $M$ , then  $C_1$  and  $C_2$  are monomially equivalent.

**Definition.** Let  $C \subseteq \mathbb{F}_q^n$  linear code. If  $G = (I_k \mid A)$ , with  $A \in M_{k, n-k}(\mathbb{F}_q)$ , is generator-matrix for  $C$ , then  $G$  is in **standard form**.

**Note.** Not every linear code has generator-matrix in standard form.

**Proposition.** Every linear code is permutation equivalent to a linear code with generator-matrix in standard form.

**Example.** Let  $C_1 \subseteq \mathbb{F}_7^5$  have generator matrix  $G_1 = \begin{bmatrix} 1 & 2 & 0 & 3 & 4 \\ 0 & 0 & 1 & 5 & 6 \end{bmatrix}$ . Then applying permutation matrix

$$P = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \Rightarrow G_1 P = \begin{bmatrix} 1 & 0 & 2 & 3 & 4 \\ 0 & 1 & 0 & 5 & 6 \end{bmatrix} = (I_2 \mid A)$$

## 9. Codes as kernels

### 9.1. Dual codes

**Definition.** Let  $C \subseteq \mathbb{F}_q^n$  linear code. **Dual** of  $C$  is

$$C^\perp := \{v \in \mathbb{F}_q^n : \forall u \in C, v \cdot u = 0\}$$

**Proposition.** If  $G$  is generator matrix for linear code  $C$  then

$$C^\perp = \{v \in \mathbb{F}_q^n : vG^T = 0\} = \ker(f_{G^T})$$

where  $f_{G^T} : \mathbb{F}_q^n \rightarrow \mathbb{F}_q^k$ ,  $f(x) = xG^T$  is linear map.

**Proposition.** Let  $C \subseteq \mathbb{F}_q^n$  linear code. Then  $C^\perp$  is also linear code and  $\dim(C) + \dim(C^\perp) = n$ .

**Proposition.** Let  $C \subseteq \mathbb{F}_q^n$  linear code, then  $(C^\perp)^\perp = C$ .

*Proof.* Show  $\dim((C^\perp)^\perp) = \dim(C)$  and  $C \subseteq (C^\perp)^\perp$ . □

**Proposition.** Let  $C \subseteq \mathbb{F}_q^n$  have generator-matrix in standard form,  $G = (I_k \mid A)$ , then  $H = (-A^T \mid I_{n-k})$  is generator-matrix for  $C^\perp$ .

*Proof.* Show  $\forall y \in \mathbb{F}_q^{n-k}, yH \in C^\perp$ , let  $f_H(y) = yH$  so  $\text{im}(f_H) \subseteq C^\perp$  and show  $\dim(\text{im}(f_H)) = \dim(C^\perp)$ .  $\square$

**Proposition.** Let  $G$  be generator matrix of  $C \subseteq \mathbb{F}_q^n$ , let  $P \in M_n(\mathbb{F}_q)$  permutation matrix such that  $GP = (I_k \mid A)$  for some  $A \in M_{k,n-k}(\mathbb{F}_q)$ . Then  $H = (-A^T \mid I_{n-k})P^T$  is generator matrix for  $C^\perp$ .

*Proof.* Similar to previous proposition, use that  $P^T = P^{-1}$ .  $\square$

**Algorithm.** To find basis for dual code  $C^\perp$ , given generator matrix  $G = (g_{ij}) \in M_{k,n}(\mathbb{F}_q)$  for  $C$  in RREF:

1. Let  $L = \{1 \leq j \leq n : G \text{ has leading 1 in column } j\}$ .
2. For each  $1 \leq j \leq n, j \notin L$ , construct  $v_j$  as follows:
  1. For  $m \notin L$ ,  $m$ th entry of  $v_j$  is 1 if  $m = j$  and 0 otherwise.
  2. Fill in the other entries of  $v_j$  (left to right) as  $-g_{1j}, \dots, -g_{kj}$ .
3. The  $n - k$  vectors  $v_j$  are basis for  $C^\perp$ .

**Example.** Let  $C \subseteq \mathbb{F}_5^7$  be linear code with generator-matrix

$$G = \begin{bmatrix} 1 & 2 & 0 & 3 & 4 & 0 & 0 \\ 0 & 0 & 1 & 1 & 2 & 0 & 3 \\ 0 & 0 & 0 & 0 & 0 & 1 & 4 \end{bmatrix}$$

Then  $L = \{1, 3, 6\}$ .

- $v_2 = (3, 1, 0, 0, 0, 0, 0)$
- $v_4 = (2, 0, 4, 1, 0, 0, 0)$
- $v_5 = (1, 0, 3, 0, 1, 0, 0)$
- $v_7 = (0, 0, 2, 0, 0, 1, 1)$
- So generator matrix for  $C^\perp$  is

$$H = \begin{bmatrix} 3 & 1 & 0 & 0 & 0 & 0 & 0 \\ 2 & 0 & 4 & 1 & 0 & 0 & 0 \\ 1 & 0 & 3 & 0 & 1 & 0 & 0 \\ 0 & 0 & 2 & 0 & 0 & 1 & 1 \end{bmatrix}$$

## 9.2. Check-matrices

**Definition.** Let  $C$  be  $[n, k]_q$  code, assume there exists  $H \in M_{n-k,n}(\mathbb{F}_q)$  with linearly independent rows, such that

$$C = \{v \in \mathbb{F}_q^n : vH^t = \mathbf{0}\}$$

Then  $H$  is **check-matrix** for  $C$ .

**Proposition.** If code  $C$  has generator-matrix  $G$  and check-matrix  $H$ , then  $C^\perp$  has check-matrix  $G$  and generator-matrix  $H$ .

*Proof.* Use Proposition 9.1.2 to show  $G$  is check-matrix for  $C^\perp$ . Show rows of  $H$  form basis for  $C^\perp$ .  $\square$

**Remark.** We can use above algorithm for the  $G \leftrightarrow H$  algorithm: obtain a generator-matrix for  $C$  from a check-matrix for  $C$ , or vice versa.

### 9.3. Minimum distance from a check-matrix

**Lemma.** Let  $C$  be  $[n, k]_q$  code,  $C = \{\mathbf{x} \in \mathbb{F}_q^n : \mathbf{x}A^T = \mathbf{0}\}$  for some  $A \in M_{m,n}(\mathbb{F}_q)$ . The following are equivalent:

- There are  $d$  linearly dependent columns of  $A$ .
- $\exists \mathbf{c} \in C : 0 < w(\mathbf{c}) \leq d$ .

*Proof.*

- $\Rightarrow$ : use definition of linear dependence, construct a *word*  $\mathbf{c}$  with  $d$  at most non-zero symbols, based on the definition. Show that  $\mathbf{c} \in C$ .
- $\Leftarrow$ : use non-zero entries of  $\mathbf{c}$  as coefficients for linear dependence between  $d$  corresponding columns of  $A$ .

□

**Example.** Let  $C = \{\mathbf{x} \in \mathbb{F}_7^5 : \mathbf{x}A^T = \mathbf{0}\}$  where

$$A = \begin{bmatrix} 3 & 1 & 1 & 4 & 1 \\ 2 & 2 & 5 & 1 & 4 \\ 6 & 3 & 5 & 0 & 2 \end{bmatrix} \in M_{3,5}(\mathbb{F}_7)$$

We have  $(0, 1, 2, 0, 4)A^T = \mathbf{0}$ . So  $(0, 1, 2, 0, 4) \in C$ , so  $C$  has codeword of weight 3. Also,  $1(1, 2, 3) + 2(1, 5, 5) + 4(1, 2, 4) = (0, 0, 0)$  so  $A$  has 3 linearly dependent columns.

**Theorem.** Let  $C = \{\mathbf{x} \in \mathbb{F}_q^n : \mathbf{x}A^T = \mathbf{0}\}$  for some  $A \in M_{m,n}(\mathbb{F}_q)$ . Then there is a linearly dependent set of  $d(C)$  columns of  $A$ , but any set of  $d(C) - 1$  columns of  $A$  is linearly independent.

*Proof.* Use [Proposition 7.2.3](#) and above lemma. □

## 10. Polynomials and cyclic codes

### 10.1. Non-prime finite fields

**Theorem.** Let  $f(x) \in \mathbb{F}_q[x]$ , then  $\mathbb{F}_q[x]/\langle f(x) \rangle$  is ring.  $\mathbb{F}_q[x]/\langle f(x) \rangle$  is field iff  $f(x)$  irreducible in  $\mathbb{F}_q[x]$ .

**Proposition.** If  $f(x) = \lambda m(x) \in \mathbb{F}_q[x]$ , with  $0 \neq \lambda \in \mathbb{F}_q$ , then

$$\mathbb{F}_q[x]/\langle f(x) \rangle = \mathbb{F}_q[x]/\langle m(x) \rangle$$

In particular, we only need to consider monic polynomials.

**Definition.**  $\alpha \in \mathbb{F}_q$  is **primitive** if

$$\mathbb{F}_q^\times = \{\alpha^j : j \in \{0, \dots, q-2\}\}$$

Every finite field has a primitive element.

**Definition.** Let  $f(x) \in \mathbb{F}_q[x]$  irreducible. If  $x$  is primitive in  $\mathbb{F}_q[x]/\langle f(x) \rangle$ , then  $f(x)$  is **primitive polynomial** over  $\mathbb{F}_q$ .

**Theorem.** Let  $q = p^r$ ,  $p$  prime,  $r \geq 2$  integer. Then there exists monic, irreducible  $f(x) \in \mathbb{F}_p[x]$  with  $\deg(f) = r$ . In particular,  $\mathbb{F}_q = \mathbb{F}_p[x]/\langle f(x) \rangle$  is field with  $q = p^r$  elements. Moreover, we can choose  $f(x)$  to be primitive.

## 10.2. Cyclic codes

**Definition.** Code  $C$  is **cyclic** if it is linear and

$$(a_0, \dots, a_{n-1}) \in C \iff (a_{n-1}, a_0, \dots, a_{n-2}) \in C$$

i.e. any cyclic shift of a codeword is also a codeword.

**Notation.** Let  $R_n = \mathbb{F}_q[x]/(x^n - 1)$ . Note  $R_n$  is not field. There is correspondence between elements in  $R_n$  and vectors in  $\mathbb{F}_q^n$ :

$$a(x) = a_0 + \dots + a_{n-1}x^{n-1} \longleftrightarrow \mathbf{a} = (a_0, \dots, a_{n-1})$$

**Lemma.** If  $a(x) \longleftrightarrow \mathbf{a}$ , then  $xa(x) \longleftrightarrow (a_{n-1}, a_0, \dots, a_{n-2})$ .

**Proposition.**  $C \subseteq R_n$  is cyclic iff  $C$  is ideal in  $R_n$ , i.e.  $a(x), b(x) \in C \implies a(x) + b(x) \in C$  and  $a(x) \in C, r(x) \in R_n \implies r(x)a(x) \in C$ .

*Proof.*

- $\implies$ : use linearity of  $C$  and Lemma 10.2.3.
- $\impliedby$ : for linearity, use  $r(x) = r_0$  constant. For cyclicity, use Lemma 10.2.3 with  $r(x) = x^m$ .

□

**Definition.** For  $f(x) \in R_n$ , the **code generated by  $f(x)$**  is

$$\langle f(x) \rangle := \{r(x)f(x) : r(x) \in R_n\}$$

**Proposition.** For any  $f(x) \in R_n$ ,  $\langle f(x) \rangle$  is cyclic code.

**Example.** Let  $R_3 = \mathbb{F}_2[x]/(x^3 - 1)$ ,  $f(x) = x^2 + 1 \in R_3$ . Then

$$\begin{aligned} \langle f(x) \rangle &= \{0, 1 + x, 1 + x^2, x + x^2\} \subseteq \mathbb{R}_3 \\ &\longleftrightarrow \{(0, 0, 0), (1, 1, 0), (1, 0, 1), (0, 1, 1)\} \subseteq \mathbb{F}_2^3 \end{aligned}$$

**Theorem.** Let  $C$  cyclic code in  $R_n$  over  $\mathbb{F}_q$ ,  $C \neq \{0\}$ . Then

- There is unique monic polynomial  $g(x)$  of smallest degree in  $C$ .
- $C = \langle g(x) \rangle$ .
- $g(x) \mid x^n - 1$ .

**Remark.** Converse of above theorem holds: every monic factor  $g(x)$  of  $x^n - 1$  is the unique generator polynomial of  $\langle g(x) \rangle$ , so distinct factors generate distinct codes. So to find all cyclic codes in  $R_n$ , find each monic divisor  $g(x)$  of  $x^n - 1$  to give cyclic code  $\langle g(x) \rangle$ .

*Proof.*

- First assume there are two such  $g(x)$  which are different, obtain contradiction.
- Use division algorithm to show  $C \subseteq \langle g(x) \rangle$  and that  $g(x) \mid x^n - 1$ .

□

**Remark.** If  $C = \{0\}$ , then setting  $g(x) = x^n - 1$ , we have  $C = \langle g(x) \rangle$ .

**Definition.** In cyclic code  $C$ , monic polynomial of minimal degree is the **generator-polynomial** of  $C$ .

**Example.** To find all binary cyclic codes of block-length 3, consider  $R_3 = \mathbb{F}_2[x]/\langle x^3 - 1 \rangle$ . In  $\mathbb{F}_2[x]$ ,  $x^3 - 1 = (x + 1)(x^2 + x + 1)$  and  $x^2 + x + 1$  is irreducible. So the possible candidates for the generator-polynomial are

generator	code in $R_3$	code in $\mathbb{F}_2^3$
1	$R_3$	$\mathbb{F}_2^3$
$x + 1$	$\{0, 1 + x, 1 + x^2, x + x^2\}$	$\{(0, 0, 0), (1, 1, 0), (1, 0, 1), (0, 1, 1)\}$
$x^2 + x + 1$	$\{0, 1 + x + x^2\}$	$\{(0, 0, 0), (1, 1, 1)\}$
$x^3 - 1$	$\{0\}$	$\{(0, 0, 0)\}$

### 10.3. Matrices for cyclic codes

**Proposition.** If  $C$  is cyclic code with generator-polynomial  $g(x) = g_0 + \dots + g_r x^r$ , then  $\dim(C) = n - r$  and  $C$  has generator-matrix

$$G = \begin{bmatrix} g_0 & g_1 & \dots & g_r & 0 & \dots & \dots & 0 \\ 0 & g_0 & g_1 & \dots & g_r & 0 & \dots & 0 \\ 0 & 0 & g_0 & g_1 & \dots & g_r & 0 & \dots \\ 0 & \dots & 0 & \ddots & \ddots & \ddots & \ddots & \ddots \\ 0 & \dots & \dots & 0 & g_0 & g_1 & \dots & g_r \end{bmatrix} \in M_{n-r, n}(\mathbb{F}_q)$$

*Proof.*

- Show  $g_0 \neq 0$ , use this to show rows are linearly independent.
- Show rows of  $G$  span  $C$  by using polynomial representation of  $C$ .

□

**Example.** Let  $C = \{(0, 0, 0), (1, 1, 0), (0, 1, 1), (1, 0, 1)\} \in \mathbb{F}_2^3$ .  $C = \langle 1 + x \rangle$  so  $\dim(C) = 3 - 1 = 2$ ,

$$G = \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \end{bmatrix}$$

**Definition.** Let  $C \subseteq R_n$  be  $[n, k]$  cyclic code with generator polynomial  $g(x)$ , let  $g(x)h(x) = x^n - 1 \in \mathbb{F}_q[x]$ . Then  $h(x)$  is the **check-polynomial** of  $C$ .

**Lemma.** Check-polynomial of cyclic  $[n, k]$  code is monic of degree  $k$ .

**Proposition.** Let  $C$  be cyclic code in  $R_n$  with check-polynomial  $h(x)$ . Then  $c(x) \in C$  iff  $c(x)h(x) = 0$  in  $R_n$ .

*Proof.*

- $\implies$ : use that  $C = \langle g(x) \rangle$ .
- $\impliedby$ : use division algorithm.

□

**Definition.** The **reciprocal polynomial** of  $h(x) = h_0 + h_1x + \dots + h_kx^k$  is

$$\bar{h}(x) = h_k + h_{k-1}x + \dots + h_0x^k = x^k h(x^{-1})$$

**Proposition.** Let  $C$  cyclic  $[n, k]$  code with check-polynomial  $h(x) = h_0 + \dots + h_kx^k$ . Then

- $C$  has check-matrix

$$H = \begin{bmatrix} h_k & h_{k-1} & \dots & h_0 & 0 & \dots & \dots & 0 \\ 0 & h_k & h_{k-1} & \dots & h_0 & 0 & \dots & 0 \\ 0 & 0 & h_k & h_{k-1} & \dots & h_0 & 0 & \dots \\ 0 & \dots & 0 & \ddots & \ddots & \ddots & \ddots & \ddots \\ 0 & \dots & \dots & 0 & h_k & h_{k-1} & \dots & h_0 \end{bmatrix}$$

- $C^\perp$  is cyclic and generated by  $\bar{h}(x)$  (i.e.  $h_0^{-1}\bar{h}(x)$  is generator-polynomial for  $C^\perp$ ).

*Proof.*

- Show that  $H$  is generator matrix for  $C^\perp$ :
  - Show rows of  $H$  are linearly independent.
  - Show rows of  $H$  are in  $C^\perp$ :
    - Let  $c(x) \in C$ , use [Proposition 10.3.5](#) to show  $c(x)h(x) = b(x)x^n - b(x)$  for some  $b(x) \in \mathbb{F}_q[x]$ ,  $\deg(b) \leq k-1$ .
- Show that  $\bar{h}(x) \mid x^n - 1$  (hint: write  $x^n = x^kx^{n-k}$ ).
- Show that if  $\bar{h}(x)$  monic, then  $\langle \bar{h}(x) \rangle$  and  $C^\perp$  have a common generator-matrix.
- If  $\bar{h}(x)$  not monic, show that multiplying by  $h_0$  is row operation, and so  $\langle \bar{h}(x) \rangle$  and  $C^\perp$  have a common generator matrix.

□

## 11. MDS and perfect codes

### 11.1. Reed-Solomon codes

**Notation.** Let  $\mathbf{P}_k = \mathbb{F}_q[z]_{<k}$  be vector space of polynomials of degree  $< k$  in  $\mathbb{F}_q$ :

$$\mathbb{F}_q[z]_{<k} = \{a_0 + \dots + a_{k-1}z^{k-1} : a_i \in \mathbb{F}_q\}$$

Dimension of  $\mathbb{F}_q[z]_{<k}$  is  $k$ .

**Definition.** Let  $0 \leq k \leq n \leq q$ ,  $\mathbf{a} = (a_1, \dots, a_n)$ ,  $\mathbf{b} = (b_1, \dots, b_n) \in \mathbb{F}_q^n$  with all  $a_j$  distinct and all  $b_j$  non-zero. Define the linear map

$$\varphi_{\mathbf{a}, \mathbf{b}} : \mathbf{P}_k \rightarrow \mathbb{F}_q^n, \quad \varphi_{\mathbf{a}, \mathbf{b}}(f(z)) := (b_1f(a_1), \dots, b_nf(a_n)) \in \mathbb{F}_q^n$$

The  $q$ -ary **Reed-Solomon code**  $\text{RS}_k(\mathbf{a}, \mathbf{b})$  is the image of  $\varphi_{\mathbf{a}, \mathbf{b}}$ :

$$\text{RS}_k(\mathbf{a}, \mathbf{b}) = \varphi_{\mathbf{a}, \mathbf{b}}(\mathbf{P}_k) \subseteq \mathbb{F}_q^n$$

**Proposition.**

- $\text{RS}_k(\mathbf{a}, \mathbf{b})$  is a  $q$ -ary  $[n, k, n - k + 1]$  code. In particular, it is an MDS code.
- A generator-matrix for  $\text{RS}_k(\mathbf{a}, \mathbf{b})$  is

$$G = (b_j a_j^{i-1})_{i,j} = \begin{bmatrix} \varphi_{\mathbf{a},\mathbf{b}}(1) \\ \vdots \\ \varphi_{\mathbf{a},\mathbf{b}}(z^{k-1}) \end{bmatrix} \in M_{k,n}(\mathbb{F}_q)$$

where  $1 \leq i \leq k$ ,  $1 \leq j \leq n$ .

*Proof.*

- To show dimension is  $k$ , show that  $\varphi_{\mathbf{a},\mathbf{b}}$  is injective, by showing it has trivial kernel.
- To show minimum distance is  $n - k + 1$ , show for  $f(z) \neq 0$  that  $w(\varphi_{\mathbf{a},\mathbf{b}}(z)) \geq n - (k - 1)$ .

□
