# 1. Basic notions in quantum information theory

The field is motivated by the fact that we want to control quantum systems.

1. Can we construct and manipulate quantum systems?
2. If so, which are the scientific and technological applications?

Entanglement frontier: highly complex quantum systems, which are more complex and richer than classical systems. However, quantum systems have *decoherence*, which classical systems don't. "Quantum advantage" gives speed up over classical systems.

Quantum vs classical information theory:

- True randomness.
- Uncertainty.
- Entanglement.

Note we always work with finite-dimensional Hilbert spaces, so take  $\mathbb{H} = \mathbb{C}^N$ .

## 1.1. Qubits and basic operations

**Notation 1.1** Vectors are denoted by  $|\psi\rangle \in \mathbb{C}^n$ , dual vectors by  $\langle\psi| \in (\mathbb{C}^n)^*$ , and inner products by  $\langle\psi|\phi\rangle \in \mathbb{C}$ .  $|\psi\rangle\langle\psi| : \mathbb{C}^n \rightarrow \mathbb{C}^n$  are rank-one projectors.

**Definition 1.2** Another important basis of  $\mathbb{C}^2$  is  $\{|+\rangle, |-\rangle\}$ , where  $|+\rangle = \frac{1}{\sqrt{2}}(|0\rangle + |1\rangle)$  and  $|-\rangle = \frac{1}{\sqrt{2}}(|0\rangle - |1\rangle)$ .

**Definition 1.3** For an operator  $T : \mathbb{H} \rightarrow \mathbb{H}$ , the **operator norm** of  $T$  is

$$\|T\| = \|T\|_{\mathbb{H} \rightarrow \mathbb{H}} := \sup_{x \in \mathbb{H}} \frac{\|T(x)\|_{\mathbb{H}}}{\|x\|_{\mathbb{H}}}$$

**Notation 1.4** Let  $\mathbb{B}(\mathbb{H})$  denote the space of bounded linear operators, i.e.  $T$  such that  $\|T\| < \infty$ .

**Notation 1.5** Denote the dual of the operator  $T$  by  $T^*$ , i.e. the operator that satisfies  $\langle y|T(x)\rangle = \langle T^*(y)|x\rangle$  for all  $x, y \in \mathbb{H}$ .

**Definition 1.6** A **quantum measurement** is a collection of measurement operators  $\{M_n\}_n \subseteq \mathbb{B}(\mathbb{H})$  which satisfies  $\sum_n M_n^* M_n = \mathbb{I}$ , the identity operator.

Given  $|\phi\rangle$ , the probability that  $|n\rangle$  occurs after this operation is  $p(n) = \langle\phi|M_n^* M_n|\phi\rangle$ . After performing this operation, the state of the system is  $\frac{1}{\sqrt{p(n)}} M_n |\phi\rangle$ . This is the

**Born rule**.

**Example 1.7** A measurement in the computational basis is  $M_0 = |0\rangle\langle 0|$ ,  $M_1 = |1\rangle\langle 1|$ . Note  $M_0$  and  $M_1$  are self-adjoint. Let  $|\psi\rangle = \alpha_0|0\rangle + \alpha_1|1\rangle$ . Then  $p(i) = \langle\phi|M_i|\phi\rangle = |\alpha_i|^2$ . The state after measurement is  $\frac{\alpha_i}{|\alpha_i|}|i\rangle$ , which is equivalent to  $|i\rangle$ .

Note that  $|\psi\rangle$  and  $e^{i\theta}|\psi\rangle$  are operationally identical: the phase does not affect the measurement probabilities.

**Definition 1.8** A quantum measurement  $\{M_n\}_n \subseteq \mathbb{B}(\mathbb{H})$  is **projective measurement** if the  $M_n$  are orthogonal projections (i.e. they are self-adjoint (Hermitian) and  $M_n M_m = \delta_{nm} M_n$ ).

**Definition 1.9** An **observable** is a Hermitian operator, which we can express as its spectral decomposition

$$M = \sum_n \lambda_n M_n,$$

where  $\{M_n\}_n$  is a projective measurement. The possible outcomes of the measurement correspond to its eigenvalues  $\lambda_n$  of the observable. Note that the expected value of the measurement is

$$\sum_n \lambda_n p(n) = \sum_n \lambda_n \langle \phi | M_n | \phi \rangle = \langle \phi | M | \phi \rangle.$$

**Definition 1.10**  $T : \mathbb{H} \rightarrow \mathbb{H}$  is **positive (semi-definite)** (written  $T \geq 0$ ) if  $\langle \psi | T | \psi \rangle \geq 0$  for all  $|\psi\rangle \in H$ .

**Definition 1.11** A **POVM (positive operator valued measurement)** is a collection  $\{E_n\}_n$  where each  $E_n = M_n^* M_n$  for a general measurement  $\{M_n\}_n$  (i.e. each  $E_n$  is positive and Hermitian, and  $\sum_n E_n = \mathbb{I}$ ).

Note that the probability of obtaining outcome  $m$  on  $|\psi\rangle$  is  $p(m) = \langle \psi | E_m | \psi \rangle$ . We use POVMs when we care only about the probabilities of the different measurement outcomes, and not the post-measurement states.

Conversely, given a POVM  $\{E_n\}_n$ , we can define a general measurement  $\{\sqrt{E_n}\}_n$ .

**Remark 1.12** Any transformation on a normalised quantum state must map it to a normalised quantum state, and so the operation must be unitary.

**Definition 1.13** The **Pauli matrices** are

$$\begin{aligned} \sigma_0 = \mathbb{I} &= \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, & \sigma_X = X &= \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}, \\ \sigma_Y = Y &= \begin{bmatrix} 0 & -i \\ i & 0 \end{bmatrix}, & \sigma_Z = Z &= \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}. \end{aligned}$$

The Pauli matrices are unitaries, and we can think of them as quantum logical gates.

**Definition 1.14** The **trace** of  $T : \mathbb{H} \rightarrow \mathbb{H}$  is

$$\text{tr } T = \text{tr } M = \sum_i M_{ii} \in \mathbb{C},$$

where  $M$  is a matrix representation of  $T$  in any basis (this is well-defined since the trace is cyclic and linear).

**Proposition 1.15** For any state  $|\phi\rangle$  and any operator  $A$ ,

$$\text{tr}(A|\phi\rangle\langle\phi|) = \langle\phi|A|\phi\rangle.$$

*Proof (Hints).* Straightforward. □

*Proof.*  $\text{tr}(A|\phi\rangle\langle\phi|) = \sum_i \langle i|A|\phi\rangle\langle\phi|i\rangle$  for an orthonormal basis  $\{|i\rangle\}$ . Any basis where  $|\phi\rangle = |j\rangle$  for some  $j$  instantly yields the result. Alternatively, we have

$$\text{tr}(A|\phi\rangle\langle\phi|) = \sum_i \langle i|A|\phi\rangle\langle\phi|i\rangle = \sum_i \langle\phi|i\rangle\langle i|A|\phi\rangle = \langle\phi|I|A|\phi\rangle = \langle\phi|A|\phi\rangle.$$

□

Suppose we don't fully know the state of the system, but know that it is  $|\phi_i\rangle$  with probability  $p_i$ . We want to be able to consider the  $\sum_i p_i |\phi_i\rangle$  as a state, but this isn't normalised (except when some  $p_i = 1$ ). To solve this issue, we assume each  $|\phi_i\rangle$  to be the rank-one projector  $|\phi_i\rangle\langle\phi_i|$ , and we describe the unknown state by  $\rho = \sum_i p_i |\phi_i\rangle\langle\phi_i|$ . This gives rise to the following definition:

**Definition 1.16** A **density matrix/operator** is a linear operator  $\rho \in \mathbb{B}(\mathbb{H})$  which is:

- Hermitian,
- Positive semi-definite, and
- Satisfies  $\text{tr } \rho = 1$ .

## 1.2. Postulates of quantum mechanics (Heisenberg picture)

**Postulate 1.17** Given an isolated physical system, there exists a complex (separable) Hilbert space  $\mathbb{H}$  associated with it, called **state space**. The physical system is described by a **state vector**, which is a normalised vector in  $\mathbb{H}$ .

**Postulate 1.18** Given an isolated physical system, its evolution is described by a unitary. If the state of the system at time  $t_1$  is  $|\phi_1\rangle$  and at time  $t_2$  is  $|\phi_2\rangle$ , then there exists a unitary  $U_{t_1, t_2}$  such that  $|\phi_2\rangle = U_{t_1, t_2} |\phi_1\rangle$ .

This can be generalised with the Schrodinger equation: the time evolution of a closed quantum system is given by  $i\hbar \frac{d}{dt} |\phi(t)\rangle = H |\phi(t)\rangle$ . The Hermitian operator  $H$  is called the **Hamiltonian** and is generally time-dependent.

**Definition 1.19** Let the spectral decomposition of  $H$  be

$$H = \sum_i E_i |E_i\rangle\langle E_i|,$$

where the  $E_i$  are the **energy eigenvalues** and the  $|E_i\rangle$  are the **energy eigenstates** (or **stationary states**).

The minimum energy is called the **ground state energy** and its associated eigenstate is called the **ground state**. The **(spectral) gap** of  $H$  is the (absolute) difference between the ground state energy and the next largest energy eigenvalue. When the gap is strictly positive, we say the system is **gapped**. The states  $|E_i\rangle$  are called **stationary**, since they evolve as  $|E_i\rangle \rightarrow \exp(-iE_i t/\hbar) |E_i\rangle$ .

We have  $|\phi(t_2)\rangle = U(t_1, t_2) |\phi(t_1)\rangle$  where  $U(t_1, t_2) = \exp(-iH(t_2 - t_1)/\hbar)$  which is a unitary. In fact, any unitary  $U$  can be written in the form  $U = \exp(iK)$  for some Hermitian  $K$ .

**Postulate 1.20** Given a physical system with associated Hilbert space  $\mathbb{H}$ , quantum measurements in the system are described by a collection of measurements  $\{M_n\}_n \subseteq \mathbb{B}(\mathbb{H})$  such that  $\sum_n M_n^* M_n = \mathbb{I}$ , as in Definition 1.6. The index  $n$  refers to the measurement outcomes that may occur in the experiment, and given a state  $|\phi\rangle$  before measurement, the probability that  $n$  occurs is

$$p(n) = \langle \phi | M_n^* M_n | \phi \rangle.$$

The state of the system after measurement is  $\frac{1}{\sqrt{p(n)}} M_n |\phi\rangle$

**Postulate 1.21** Given a composite physical system, its state space  $\mathbb{H}$  is also composite and corresponds to the tensor product of the individual state spaces  $\mathbb{H}_i$  of each component:  $\mathbb{H} = \mathbb{H}_1 \otimes \cdots \otimes \mathbb{H}_N$ . If the state in each system  $i$  is  $|\phi_i\rangle$ , then the state in the composite system is  $|\phi_1\rangle \otimes \cdots \otimes |\phi_N\rangle$ .

**Definition 1.22** Given  $|\phi\rangle \in H_1 \otimes \cdots \otimes H_N$ ,  $|\phi\rangle$  is **entangled** if it cannot be written as a tensor product of the form  $|\phi_1\rangle \otimes \cdots \otimes |\phi_n\rangle$ . Otherwise, it is **separable** or a **product state**.

**Example 1.23** The **EPR pair (Bell state)**  $|\phi^+\rangle = \frac{1}{\sqrt{2}}(|00\rangle + |11\rangle)$  is entangled.

### 1.3. Postulates of quantum mechanics (Schrodinger picture)

**Postulate 1.24** Given an isolated physical system, the state of the system is completely described by its density operator, which is Hermitian, positive semi-definite and has trace one.

If we know the system is in state  $\rho_i$  with probability  $p_i$ , then the state of the system is  $\sum_i p_i \rho_i$ .

**Pure states** are of the form  $\rho = |\phi\rangle\langle\phi|$ , **mixed states** are of the form  $\rho = \sum_i p_i |\phi_i\rangle\langle\phi_i|$ .

**Postulate 1.25** Given an isolated physical system, its evolution is described by a unitary. If the state of the system is  $\rho_1$  at time  $t_1$  and is  $\rho_2$  at time  $t_2$ , then there is a unitary  $U$  depending only on  $t_1, t_2$  such that  $\rho_2 = U \rho_1 U^*$ .

**Postulate 1.26** The same as Postulate 1.20, except we specify that after measurement  $\{M_n\}_n$ , the probability of observing  $n$  is  $p(n) = \text{tr}(M_n^* M_n \rho)$  and the state after measurement is  $\frac{1}{\sqrt{p(n)}} M_n \rho M_n^*$ .

**Postulate 1.27** The same as Postulate 1.21, except that the state of the composite system is  $\rho = \rho_1 \otimes \cdots \otimes \rho_n$ , where  $\rho_i$  is the state of  $i$ th individual system.

**Remark 1.28** The Heisenberg and Schrodinger postulates are mathematically equivalent.

### 1.4. States, entanglement and measurements

**Theorem 1.29** (Schmidt Decomposition) Let  $|\psi\rangle$  be a pure state in a bipartite system  $\mathbb{H}_{AB} = \mathbb{H}_A \otimes \mathbb{H}_B$ , where  $\mathbb{H}_A$  has dimension  $N_A$  and  $\mathbb{H}_B$  has dimension  $N_B \geq N_A$ . Then

there exist orthonormal states  $\{|e_i\rangle : i \in [N_A]\} \subseteq \mathbb{H}_A$  and  $\{|f_i\rangle : i \in [N_A]\} \subseteq \mathbb{H}_B$  such that

$$|\psi\rangle = \sum_{i=1}^{N_A} \lambda_i |e_i\rangle \otimes |f_i\rangle,$$

where  $\lambda_i \geq 0$  and  $\sum_i \lambda_i^2 = 1$ .

The  $\lambda_i$  are unique up to re-ordering. The  $\lambda_i$  are called the **Schmidt coefficients** and the number of  $\lambda_i > 0$  is the **Schmidt rank** of the state.

*Proof (Hints).* Use the singular value decomposition of the matrix of amplitudes of  $|\psi\rangle$ .  $\square$

*Proof.* Let  $|\psi\rangle = \sum_{k=1}^{N_A} \sum_{\ell=1}^{N_B} \beta_{k\ell} |\phi_k\rangle \otimes |\chi_\ell\rangle$  for orthonormal bases  $\{|\phi_k\rangle : k \in [N_A]\} \subseteq \mathbb{H}_A$ ,  $\{|\chi_\ell\rangle : \ell \in [N_B]\} \subseteq \mathbb{H}_B$ . Let  $(\beta_{k\ell})$  have singular value decomposition

$$U[\Sigma \ 0]V,$$

where  $U$  is an  $N_A \times N_A$  unitary,  $\Sigma$  is an  $N_A \times N_A$  diagonal matrix with non-negative entries, and  $V$  is an  $N_B \times N_B$  unitary. So

$$\beta_{k\ell} = \sum_{i=1}^{N_A} \sum_{j=1}^{N_B} U_{ki} \Sigma_{ij} V_{j\ell} = \sum_{i=1}^{N_A} \Sigma_{ii} U_{ki} V_{i\ell}.$$

Hence,

$$|\psi\rangle = \sum_{k,\ell} \sum_i \Sigma_{ii} U_{ki} |\phi_k\rangle \otimes V_{i\ell} |\chi_\ell\rangle = \sum_i \Sigma_{ii} \underbrace{\left( \sum_k U_{ki} |\phi_k\rangle \right)}_{|e_i\rangle} \otimes \underbrace{\left( \sum_\ell V_{i\ell} |\chi_\ell\rangle \right)}_{|f_i\rangle}.$$

$\square$

**Proposition 1.30**  $|\psi\rangle$  is entangled iff its Schmidt rank is  $> 1$ . Otherwise, it is separable (i.e. a product state).

**Definition 1.31** Let  $|\psi\rangle$  be a pure state in a bipartite system  $\mathbb{H}_{AB} = \mathbb{H}_A \otimes \mathbb{H}_B$ , where  $\mathbb{H}_A$  has dimension  $N_A$  and  $\mathbb{H}_B$  has dimension  $N_B \geq N_A$ .  $|\psi\rangle$  is **maximally entangled** if all its Schmidt coefficients are equal (to  $1/\sqrt{N_A}$ ).

**Notation 1.32** Write  $\mathbb{S}(\mathbb{H}) = \{\rho \in \mathbb{B}(\mathbb{H}) : \rho = \rho^\dagger, \rho \geq 0, \text{tr } \rho = 1\}$  for the set of density matrices on  $\mathbb{H}$ .

**Definition 1.33** The **partial trace** over  $B$ ,  $\text{tr}_B$ , on the bipartite system  $\mathbb{H}_{AB} = \mathbb{H}_A \otimes \mathbb{H}_B$  is the operator defined linearly by

$$\begin{aligned} \text{tr}_B : \mathbb{S}(\mathbb{H}_{AB}) &\rightarrow \mathbb{S}(\mathbb{H}_A), \\ |a_1\rangle\langle a_2| \otimes |b_1\rangle\langle b_2| &\mapsto \text{tr}(|b_1\rangle\langle b_2|) \cdot |a_1\rangle\langle a_2|. \end{aligned}$$

Note that if  $\rho_{AB} = \rho_A \otimes \rho_B$ , then  $\text{tr}_B \rho_{AB} = \text{tr}(\rho_B) \cdot \rho_A = \rho_A$ .

**Definition 1.34** Let  $\rho_{AB}$  be a density matrix in  $\mathbb{S}(\mathbb{H}_{AB})$ .  $\rho_A = \text{tr}_B(\rho_{AB})$  is called the **reduced density matrix** or **marginal** of  $\rho_{AB}$  in  $A$

**Proposition 1.35** Let  $M_A \in B(\mathbb{H}_A)$ . We have

$$\text{tr}(M_A \rho_A) = \text{tr}((M_A \otimes \mathbb{I}_B) \rho_{AB}).$$

for all  $\rho_{AB} \in \mathbb{S}(\mathbb{H}_{AB})$ ,  $\rho_A = \text{tr}_B(\rho_{AB})$ . In fact, this can be taken to be an equivalent definition of partial trace.

**Remark 1.36** Let  $\rho_{AB} = |\psi\rangle\langle\psi| \in \mathbb{S}(\mathbb{H}_{AB})$  be a pure state and let  $r_\psi$  be its Schmidt rank. Then

$$\rho_A = \text{tr}_B(|\psi\rangle\langle\psi|) = \sum_{k=1}^{r_\psi} p_k |u_k\rangle\langle u_k|.$$

So  $\rho_A$  is pure iff  $r_\psi = 1$ , i.e. iff  $|\psi\rangle$  is separable.

**Proposition 1.37** Let  $\rho_{AB} \in B(\mathbb{H}_{AB})$  and  $\rho_A = \text{tr}_B(\rho_{AB})$ . Then:

1.  $\text{tr} \rho_A = \text{tr} \rho_{AB}$ .
2. If  $\rho_{AB} \geq 0$ , then  $\rho_A \geq 0$ .
3. If  $\rho_{AB}$  is a density matrix then  $\rho_A$  is a density matrix.
4. We have

$$\langle \phi_i | \rho_A | \phi_i \rangle = \sum_k \langle \phi_i \otimes \psi_k | \rho_{AB} | \phi_i \otimes \psi_k \rangle,$$

for an orthonormal bases  $\{|\phi_i\rangle\}$  and  $\{|\psi_k\rangle\}$ .

5. If  $\rho_{AB} = \sigma_A \otimes \sigma_B$  and  $\text{tr}(\sigma_B) = 1$ , then  $\sigma_A = \rho_A$ .

*Proof (Hints).*

1. Straightforward.
2. Use Proposition [1.35](#).
3. Straightforward.

□

*Proof.*

1. This follows from linearity of trace and the fact that  $\text{tr}(\rho \otimes \sigma) = \text{tr}(\rho) \cdot \text{tr}(\sigma)$ .
2. By Proposition [1.35](#),

$$\begin{aligned} \langle \psi | \rho_A | \psi \rangle &= \text{tr}(\rho_A |\psi\rangle\langle\psi|) = \text{tr}(\rho_{AB}(|\psi\rangle\langle\psi| \otimes \mathbb{I})) \\ &= \sum_i \text{tr}(\rho_{AB} |\psi\rangle\langle\psi| \otimes |i\rangle\langle i|) = \sum_i (\langle \psi | \otimes \langle i |) \rho_{AB} (|\psi\rangle \otimes |i\rangle) \geq 0. \end{aligned}$$

3. From 1 and 2, by definition.

□

**Definition 1.38** Let  $\rho_A \in \mathbb{S}(H_A)$  be a (pure or mixed) state. We may introduce an auxiliary space  $\mathbb{H}_R$  of dimension  $\text{rank}(\rho_A)$  and construct a pure state  $|\psi_{AR}\rangle \in \mathbb{H}_A \otimes \mathbb{H}_R$  such that  $\rho_A = \text{tr}_R(|\psi_{AR}\rangle\langle\psi_{AR}|)$ . This is called **purification**.

**Remark 1.39** Let  $\{M_n^A\}_n$  be a POVM in  $\mathbb{H}_A$ . Then  $\{M_n^A \otimes \mathbb{I}_B\}_n$  is a POVM in  $\mathbb{H}_{AB}$ .

**Theorem 1.40** (Naimark) For every POVM  $\{E_n\}_{n=1}^m \subseteq \mathbb{B}(\mathbb{H})$ , there is a state  $|\psi\rangle \in \mathbb{C}^m$  and a projective measurement  $\{P_n\}_{n=1}^m \subseteq \mathbb{B}(\mathbb{H} \otimes \mathbb{C}^m)$  such that

$$\text{tr}(\rho E_n) = \text{tr}((\rho \otimes |\psi\rangle\langle\psi|)P_n) \quad \forall n \in [m], \forall \rho \in \mathbb{S}(\mathbb{H}).$$

## 2. Quantum channels and open systems

### 2.1. Quantum channels

**Definition 2.1** A **quantum channel** is a linear map  $T : \mathbb{S}(\mathbb{H}_{\text{in}}) \rightarrow \mathbb{S}(\mathbb{H}_{\text{out}})$  which satisfies:

- **Preserves trace:**  $\text{tr}(T(\rho)) = \text{tr}(\rho)$  for all  $\rho \in \mathbb{S}(\mathbb{H}_{\text{in}})$ .
- **Positive:** if  $\rho \geq 0$ , then  $T(\rho) \geq 0$ .
- **Completely positive:** for all  $n \in \mathbb{N}$ ,  $(T \otimes \mathbb{I}_n)$  is positive (note that this implies the second condition, but the converse is false).

So quantum channels are completely positive trace-preserving (CPTP) maps. We may depict a quantum channel  $T$  as follows:

**Example 2.2** Examples of quantum channels:

- Unitary evolution:  $\rho \mapsto U\rho U^*$ .
- Adding an ancilla:  $\rho \mapsto \rho \otimes \rho_E$  (the  $E$  denotes “environment”).
- Partial trace:  $\rho \mapsto \text{tr}_B(\rho)$  or  $\rho \mapsto \text{tr}_A(\rho)$ .

We will see that in fact, any quantum channel is a combination of these three.

**Definition 2.3** We define the **maximally entangled state** in  $(\mathbb{C}^d)^{\otimes 2}$  as

$$|\phi\rangle = \frac{1}{\sqrt{d}} \sum_{k=1}^d |kk\rangle.$$

**Definition 2.4** Recall the transposition map is defined as

$$\Theta : A \rightarrow A^T, \quad \langle i|A^T|j\rangle = \langle j|A|i\rangle.$$

We define the **partial transpose** by its action on the maximally entangled state  $|\phi\rangle = \frac{1}{\sqrt{d}} \sum_{i=1}^d |ii\rangle$ :

$$(|\phi\rangle\langle\phi|)^{T_A} = (|\phi\rangle\langle\phi|)^{T_1} = (\Theta \otimes \text{id})(|\phi\rangle\langle\phi|) = \frac{1}{d}F,$$

where  $F = \sum_{i,j=1}^n |ij\rangle\langle ji|$  is the flip operator. Note the partial transpose is positive but not CP. Alternatively, we can define it by its action on an orthonormal basis:

$$\langle ij|X^{T_A}|k\ell\rangle = \langle kj|X|i\ell\rangle.$$

**Remark 2.5** Note that the partial transpose is useful for detecting entanglement but is not physically implementable (as not CP).

**Definition 2.6** The **Hilbert-Schmidt inner product** of  $A, B \in B(\mathbb{C}^d)$  is

$$\langle A|B\rangle_{\text{HS}} := \text{tr}(A^*B).$$

**Definition 2.7** Let  $T : B(\mathbb{C}^d) \rightarrow B(\mathbb{C}^{d'})$  be a linear map. The **adjoint** of  $T$  is the unique linear map  $T^* : B(\mathbb{C}^{d'}) \rightarrow B(\mathbb{C}^d)$  which satisfies

$$\langle T(A), B \rangle_{\text{HS}} = \langle A, T^*(B) \rangle_{\text{HS}} \quad \forall A \in B(\mathbb{C}^d), B \in B(\mathbb{C}^{d'}).$$

**Definition 2.8** Let  $T : B(\mathbb{C}^d) \rightarrow B(\mathbb{C}^{d'})$  be a linear map. The **Choi-Jamiolkowski matrix**  $C \in B(\mathbb{C}^{d'} \otimes \mathbb{C}^d)$  of  $T$  is defined as

$$C := (T \otimes \text{id}_d)|\phi\rangle\langle\phi|.$$

Note that in fact,  $C \in S(\mathbb{C}^{d'} \otimes \mathbb{C}^d)$  is a density matrix if  $T$  is a quantum channel.

**Remark 2.9** Note that the Choi-Jamiolkowski matrix completely determines  $T$ : since  $|\phi\rangle\langle\phi| = \frac{1}{d} \sum_{n,m=1}^d |nn\rangle\langle mm|$ , we have

$$\begin{aligned} \langle ij|C|k\ell\rangle &= \frac{1}{d} \sum_{m,n=1}^d \langle ij|(T(|n\rangle\langle m|) \otimes |n\rangle\langle m|)|k\ell\rangle \\ &= \frac{1}{d} \sum_{m,n=1}^d \langle j|n\rangle \cdot \langle m|\ell\rangle \cdot \langle i|T(|n\rangle\langle m|)|k\rangle = \frac{1}{d} \langle i|T(|j\rangle\langle\ell|)|k\rangle, \end{aligned}$$

and so we can determine any entry of any  $T(\rho)$  by linearity. This state-channel duality is called the **Choi-Jamiolkowski isomorphism**, and can be expressed as

$$\text{tr}(AT(B)) = d \text{tr}(C(A \otimes B^T)) \quad \forall A \in B(\mathbb{C}^{d'}), B \in B(\mathbb{C}^d).$$

Indeed, let  $\mathbb{F}|ij\rangle = |ji\rangle$  be the flip operator: note that  $\mathbb{F}^{T_2} = d|\phi\rangle\langle\phi|$ , then if  $d = d'$ ,

$$\begin{aligned} d \text{tr}(C(A \otimes B^T)) &= d \text{tr}((T \otimes \text{id}_d)(|\phi\rangle\langle\phi|)(A \otimes B^T)) \\ &= \text{tr}((T \otimes \text{id}_d)\mathbb{F}^{T_2}(A \otimes B^T)) \\ &= \text{tr}(\mathbb{F}^{T_2}(T^*(A) \otimes B^T)) = \text{tr}(T^*(A) \otimes B) = \text{tr}(AT(B)). \end{aligned}$$

**Theorem 2.10** (Characterisation of Quantum Channels) Let  $T : B(\mathbb{C}^d) \rightarrow B(\mathbb{C}^{d'})$  be a linear map. TFAE:

1.  $T$  is a quantum channel.
2. Let  $C = (T \otimes \mathbb{I}_d)(|\phi\rangle\langle\phi|)$  be the Choi-Jamiolkowski matrix of  $T$ , then  $C \geq 0$  and  $\text{tr}_1(C) = \frac{1}{d}\mathbb{I}_d$ .
3. **Kraus decomposition:** There exists  $\{A_k\}_{k=1}^{dd'} \subseteq \mathbb{C}^{d' \times d}$  with  $\sum_{k=1}^{dd'} A_k^* A_k = \mathbb{I}_d$  such that

$$T(\rho) = \sum_{k=1}^{dd'} A_k \rho A_k^* \quad \forall \rho \in S(\mathbb{C}^d).$$

We call the number of non-trivial  $A_k$  in the Kraus decomposition the **Kraus rank** of  $T$ .

4. **Stinespring dilation:** there exists a unitary  $U$  on  $\mathbb{C}^d \otimes \mathbb{C}^{dd'}$  and a state  $|\psi\rangle \in \mathbb{C}^{dd'}$  such that  $T(\rho) = \text{tr}_2(U(\rho \otimes |\psi\rangle\langle\psi|)U^*)$  for all  $\rho \in S(\mathbb{C}^d)$ .

*Proof (Hints).*

- $1 \Rightarrow 2$ : straightforward.
- $4 \Rightarrow 1$ : use that compositions of quantum channels are quantum channels.

□

*Proof.*

- $1 \Rightarrow 2$ :  $C \geq 0$  follows from the completely positive property of  $T$  and linearity. Also,

$$\begin{aligned} \text{tr}_1(C) &= \frac{1}{d} \sum_{n,m=1}^d \text{tr}(T|n\rangle\langle m|) \cdot |n\rangle\langle m| \\ &= \frac{1}{d} \sum_{n,m=1}^d \text{tr}(|n\rangle\langle m|) \cdot |n\rangle\langle m| \quad \text{since } T \text{ preserves trace} \\ &= \frac{1}{d} \sum_{n,m} \delta_{mn} |n\rangle\langle m| = \frac{1}{d} \sum_{n=1}^d |n\rangle\langle n| = \frac{1}{d} \mathbb{I}_d. \end{aligned}$$

- $2 \Rightarrow 3$ : we use that (verify this)  $(A \otimes \mathbb{I})|\phi\rangle = (\mathbb{I} \otimes A^T)|\phi\rangle$  for all  $A \in B(\mathbb{C}^d)$ , where  $|\phi\rangle$  is the maximally entangled state, and that  $\forall |\psi\rangle \in \mathbb{C}^{d^2}$ , there exists  $A$  such that  $|\psi\rangle = (A \otimes \mathbb{I})|\phi\rangle$ . Since  $C \geq 0$ , we can write  $C = \sum_{k=1}^{dd'} |\psi_k\rangle\langle\psi_k|$  ( $|\psi_k\rangle$  are not necessarily normalised). So

$$\begin{aligned} C &= \sum_{k=1}^{dd'} (A_k \otimes \mathbb{I})|\phi\rangle\langle\phi|(A_k^* \otimes \mathbb{I}) \\ &= (T \otimes \mathbb{I})|\phi\rangle\langle\phi|. \end{aligned}$$

Also,

$$\begin{aligned} \frac{1}{d} \mathbb{I} &= \text{tr}_1(C) = \sum_{n=1}^d \langle n_1 | C_{12} | n_1 \rangle \\ &= \frac{1}{d} \sum_{n=1}^d \sum_{m=1}^{dd'} (\mathbb{I} \otimes A_m^T) (|\phi\rangle\langle\phi|) (\mathbb{I} \otimes \bar{A}_m) |n\rangle \\ &= \sum_{n=1}^d \langle n | \sum_{k=1}^{dd'} (\mathbb{I} \otimes A_m^T) \frac{1}{d} \left( \sum_{k,\ell=1}^d |kk\rangle\langle\ell\ell| \right) (\mathbb{I} \otimes \bar{A}_m) |n\rangle \\ &= \frac{1}{d} \sum_{n=1}^d \sum_{m=1}^{dd'} \sum_{k,\ell=1}^d \langle n | k \rangle \langle \ell | n \rangle A_m^T |k\rangle \langle \ell | \bar{A}_m \end{aligned}$$

$$\begin{aligned}
&= \frac{1}{d} \sum_{n=1}^d \sum_{m=1}^{dd'} A_m^T |n\rangle \langle n| \bar{A}_m \\
&= \frac{1}{d} \sum_{m=1}^{dd'} A_m^T \bar{A}_m
\end{aligned}$$

So we set  $\tilde{A}_m := \bar{A}_m$ .

- $3 \Rightarrow 4$ : let  $V = \sum_{k=1}^{dd'} A_k \otimes |k\rangle$ , where  $\{|k\rangle\}_{k=1}^{dd'}$  is an orthonormal basis of  $\mathbb{C}^{dd'}$ .  $V$  is an isometry, i.e.  $V^*V = \sum_{k=1}^{dd'} A_k^* A_k = \mathbb{I}_d$ . Then for all  $\rho \in S(\mathbb{C}^{dd'})$ , since  $(A_k \otimes |k\rangle)\rho = (A_k \rho) \otimes |k\rangle$ ,

$$\begin{aligned}
\text{tr}_2(V\rho V^*) &= \text{tr}_2\left(\sum_{k,\ell=1}^{dd'} (A_k \rho A_\ell^*) \otimes |k\rangle \langle \ell|\right) \\
&= \sum_{k,\ell=1}^{dd'} (A_k \rho A_\ell^*) \text{tr}(|k\rangle \langle \ell|) \\
&= \sum_{k=1}^{dd'} A_k \rho A_k^* = T(\rho).
\end{aligned}$$

Now choose  $V = U(\mathbb{I} \otimes |\psi\rangle)$  for some pure state  $|\psi\rangle$  and unitary  $U$ .

- $4 \Rightarrow 1$ : the maps

$$\rho \mapsto \rho \otimes |\psi\rangle \langle \psi| \mapsto U(\rho \otimes |\psi\rangle \langle \psi|)U^* \mapsto \text{tr}_2(U(\rho \otimes |\psi\rangle \langle \psi|)U^*)$$

are all quantum channels, and so their composition is also a quantum channel. □

### Remark 2.11

- The number  $k$  in the Kraus decomposition is called the **Kraus rank** of  $T$ , which is the same as the Choi rank (rank of the Choi-Jamiolkowski matrix). Note: this is not the same as the rank of  $T$  as a map.
- We can always express  $T$  with  $r = \text{rank}(C)$  Kraus operators which are orthogonal (w.r.t Hilbert-Schmidt inner product), since  $T$  is a completely positive linear map.
- Two sets of Kraus operator  $\{K_j\}$  and  $\{J_\ell\}$  represent the same map  $T$  iff there exists a unitary  $U$  such that  $K_j = \sum_\ell U_{j\ell} J_\ell$ .

## 2.2. Examples of quantum channels

**Definition 2.12** In two dimensions, there are three kinds of errors:

1. Bit flip errors, modelled by the Pauli  $X$ :  $|0\rangle \mapsto |1\rangle$ ,  $|1\rangle \mapsto |0\rangle$ .
2. Phase flip error: modelled by Pauli  $Z$ :  $|0\rangle \mapsto |0\rangle$ ,  $|1\rangle \mapsto -|1\rangle$ .
3. Combination of bit and phase flip errors: modelled by Pauli  $Y$ .

A map describing the depolarising channel is

$$U_{A \rightarrow AE} : |\psi\rangle_A \mapsto \sqrt{1-p} |\psi\rangle_A \otimes |0\rangle_E + \sqrt{\frac{p}{3}} (X|\psi\rangle_A \otimes |1\rangle_E + Y|\psi\rangle_A \otimes |2\rangle_E + Z|\psi\rangle_A \otimes |3\rangle_E)$$

(the environment  $H_E$  has dimension 4). We can express this in the Kraus decomposition: let  $M_a := \langle a|_E U_{A \rightarrow AE}$ ,  $a \in \{0, 1, 2, 3\}$ , and  $M_0 = \sqrt{1-p}\mathbb{I}$ ,  $M_1 = \sqrt{p/3}X$ ,  $M_2 = \sqrt{p/3}Y$ ,  $M_3 = \sqrt{p/3}Z$ . It is straightforward to see that

$$\sum_{a=0}^3 M_a^\dagger M_a = \left(1 - p + \frac{p}{3} + \frac{p}{3} + \frac{p}{3}\right) \mathbb{I} = \mathbb{I}.$$

The channel is  $T(\rho) = (1-p)\rho + \frac{p}{3}(X\rho X + Y\rho Y + Z\rho Z)$ . For arbitrary dimensions  $D$ , the depolarising channel is  $\rho \mapsto (1-p)\rho + p\sigma$ , where  $\sigma \in S(\mathbb{C}^D)$ , usually  $\sigma = \mathbb{I}/d$ .

**Definition 2.13** The **phase damping channel** is the map

$$\rho = \begin{bmatrix} \rho_{00} & \rho_{01} \\ \rho_{10} & \rho_{11} \end{bmatrix} \mapsto \begin{bmatrix} \rho_{00} & (1-p)\rho_{01} \\ (1-p)\rho_{10} & \rho_{11} \end{bmatrix}.$$

Let the environment have orthonormal basis  $\{|0\rangle, |1\rangle, |2\rangle\}$ , then the state representation is

$$\begin{aligned} |0\rangle_A &\mapsto \sqrt{1-p}|0\rangle_A \otimes |0\rangle_E + \sqrt{p}|0\rangle_A \otimes |1\rangle_E \\ |1\rangle_A &\mapsto \sqrt{1-p}|1\rangle_A \otimes |0\rangle_E + \sqrt{p}|1\rangle_A \otimes |2\rangle_E \end{aligned}$$

The Kraus operators are  $M_0 = \sqrt{1-p} \cdot \mathbb{I}$ ,  $M_1 = \sqrt{p}|0\rangle\langle 0|$ ,  $M_2 = \sqrt{p}|1\rangle\langle 1|$ . We have  $M_0^2 + M_1^2 + M_2^2 = \mathbb{I}$ . The map is  $T(\rho) = (1-p/2)\rho + \frac{1}{2}pZ\rho Z$ .

**Definition 2.14** A density matrix  $\rho \in \mathbb{S}(\mathbb{H}_A \otimes \mathbb{H}_B)$  is **separable** if it can be expressed as a convex combination

$$\rho = \sum_i p_i \rho_i^A \otimes \sigma_i^B,$$

where  $p_i \geq 0$ ,  $\sum_i p_i = 1$ , and  $\rho_i^A \in \mathbb{S}(\mathbb{H}_A)$  and  $\sigma_i^B \in \mathbb{S}(\mathbb{H}_B)$ .

**Definition 2.15** A quantum channel  $T$  is **entanglement breaking** if its Choi-Jamiolkowski matrix is separable. This is equivalent to the existence of a POVM  $\{M_k\}$  and a set of density matrices  $\{\rho_k\}$  such that  $T(\rho) = \sum_k \text{tr}(M_k \rho) \rho_k$ .

## 2.3. Properties of channels

**Remark 2.16** Let  $|\psi\rangle \in \mathbb{H}_A \otimes \mathbb{H}_B$ ,  $d = \min\{\dim H_A, \dim H_B\}$ , not necessarily normalised. The Schmidt decomposition is

$$|\psi\rangle = \sum_{j=1}^d \lambda_j |e_j\rangle \otimes |f_j\rangle,$$

where  $\lambda_j \geq 0$ ,  $\sum_{j=1}^d \lambda_j^2 = \langle \psi | \psi \rangle$ , and  $\{|e_j\rangle : j \in [d]\}$  and  $\{|f_j\rangle : j \in [d]\}$  orthonormal bases.

The reduced density operators of  $|\psi\rangle$  are diagonal in the bases  $\{|e_j\rangle\}$ ,  $\{|f_j\rangle\}$ , with eigenvalues  $\lambda_j^2$ . Conversely, if  $\rho_A \in \mathbb{S}(\mathbb{H}_A)$  has spectral decomposition  $\rho_A = \sum_j \lambda_j |e_j\rangle\langle e_j|$ , then  $|\psi\rangle$  provides a purification for  $\rho_A = \text{tr}_B(|\psi\rangle\langle\psi|)$ ; the minimal dilation space we can choose,  $\mathbb{H}_{\min}$  has dimension  $\text{rank}(\rho_A)$ . If  $|\psi\rangle \in \mathbb{H}_A \otimes \mathbb{H}_{\min}$ , then all other purifications

of  $\rho_A$  are of the form  $|\psi'\rangle = (\mathbb{I}_A \otimes V)|\psi\rangle$ , with  $V \in B(\mathbb{H}_{\min}, \mathbb{H}_B)$  an isometry. Hence, all purifications are related by  $\mathbb{I}_A \otimes U$  with  $U$  an isometry.

**Proposition 2.17** (Equivalence of Ensembles) Let  $\{|\psi_j\rangle : j \in [M]\}$  and  $\{|\phi_\ell\rangle : \ell \in [N]\}$  be (not necessarily normalised) ensembles. Then

$$\sum_{j=1}^M |\psi_j\rangle\langle\psi_j| = \sum_{\ell=1}^N |\phi_\ell\rangle\langle\phi_\ell|$$

iff there is an isometry  $U \in \mathbb{C}^{M \times N}$  such that  $|\psi_j\rangle = \sum_{\ell=1}^N U_{j\ell} |\phi_\ell\rangle$ .

*Proof (Hints).*

- $\Leftarrow$ : straightforward.
- $\Rightarrow$ : explain why we can assume that  $\rho = \sum_j |\psi_j\rangle\langle\psi_j|$  and  $\sigma = \sum_\ell |\phi_\ell\rangle\langle\phi_\ell|$  are density matrices. Consider purifications of  $\rho$  and  $\sigma$  which use the same orthonormal basis in the dilation space.

□

*Proof.*

- $\Leftarrow$ : this is straightforward to show.
- $\Rightarrow$ : WLOG (by rescaling  $\rho$ ), we can assume  $\rho := \sum_j |\psi_j\rangle\langle\psi_j|$  is a density matrix. We have  $\rho = \text{tr}_B(|\psi\rangle\langle\psi|)$  (through purification), where  $|\psi\rangle = \sum_j |\psi_j\rangle \otimes |j\rangle$ . Similarly, let  $|\phi\rangle = \sum_\ell |\phi_\ell\rangle \otimes |\ell\rangle$  (so we use the same orthonormal basis  $\{|\ell\rangle\} = \{|j\rangle\}$ ). So  $|\psi\rangle$  and  $|\phi\rangle$  differ by a unitary (or an isometry if the dimensions are not equal), hence  $|\psi\rangle = (1 \otimes U)|\phi\rangle$ . Taking the scalar product with  $\langle j|$ , we obtain  $|\psi_j\rangle = \sum_\ell U_{j\ell} |\phi_\ell\rangle$ .

□

**Notation 2.18** Let  $T_1, T_2$  be linear maps. Write  $T_2 \geq T_1$  to mean  $T_2 - T_1$  is completely positive. By the Choi-Jamiołkowski isomorphism, this is equivalent to  $C_2 \geq C_1$  where  $C_i$  is the Choi matrix of  $T_i$  (i.e.  $C_2 - C_1$  is positive semi-definite).

**Theorem 2.19** Let  $T_1, T_2 : \mathbb{C}^{d' \times d'} \rightarrow \mathbb{C}^{d \times d}$  be completely positive maps, with  $T_2 \geq T_1$ . Let  $V_i : \mathbb{C}^d \rightarrow \mathbb{C}^{d'} \otimes \mathbb{C}^{r_i}$  be Stinespring representations for  $T_i$  (i.e.  $T_i(A) = V_i^* (A \otimes \mathbb{I}_{r_i}) V_i$ ), then there is a contraction (i.e.  $W^* W \leq \mathbb{I}$ )  $W : \mathbb{C}^{r_2} \rightarrow \mathbb{C}^{r_1}$  such that  $V_1 = (\mathbb{I}_{d'} \otimes W) V_2$ .

Moreover, if  $V_2$  belongs to a minimal dilation, then  $W$  is unique.

*Proof (Hints).*

□

*Proof.* We use the equivalence  $T_2 \geq T_1 \Leftrightarrow C_2 \geq C_1$ . Define the map

$$R_i = (\mathbb{I}_{r_i} \otimes \langle\phi|)(V_i \otimes \mathbb{I}_{d'}) \in B(\mathbb{C}^d \otimes \mathbb{C}^{d'}, \mathbb{C}^{r_i})$$

Let  $|\psi\rangle \in \mathbb{C}^d \otimes \mathbb{C}^{d'}$ . We want to show  $\|R_2|\psi\rangle\|^2 \geq \|R_1|\psi\rangle\|^2$ . Indeed,

$$\|R_2|\psi\rangle\|^2 = \langle\psi| R_2^* R_2 |\psi\rangle$$

$$\begin{aligned}
&= \langle \psi | (V_2^* \otimes \mathbb{I}_{d'}) (\mathbb{I}_{r_2} \otimes |\phi\rangle) (\mathbb{I}_{r_2} \otimes \langle \phi|) (V_2 \otimes \mathbb{I}_{d'}) | \psi \rangle \\
&= \langle \psi | (T_2 \otimes \text{id}) (|\phi\rangle \langle \phi|) \\
&= \langle \psi | C_2 | \psi \rangle \geq \langle \psi | C_1 | \psi \rangle.
\end{aligned}$$

And  $\langle \psi | C_1 | \psi \rangle = \|R_1 | \psi \rangle\|^2$  by the same argument. So there exists a contraction  $W : \mathbb{C}^{r_2} \rightarrow \mathbb{C}^{r_1}$ , such that  $R_1 = WR_2$ . So  $V_1 = (\mathbb{I}_{d'} \otimes W)V_2$ . If  $r_2 = \text{rank}(C_2)$ , then  $R_2$  is surjective, and so  $W$  is uniquely determined.  $\square$

**Theorem 2.20** (Radon-Nikodym) Let  $\{T_i\}$  be a set of CP maps such that  $\sum_i T_i = T \in B(\mathbb{C}^{d' \times d'}, \mathbb{C}^{d \times d})$  with Stinespring representation  $T(A) = V^*(A \otimes \mathbb{I}_r)V$ . Then there exists a set of non-negative operators  $P_i \in \mathbb{C}^{r \times r}$  such that  $\sum_i P_i = \mathbb{I}_r$  and  $T_i(A) = V^*(A \otimes P_i)V$ .

**Remark 2.21** Since  $T = \sum_i T_i$ , this gives  $T(A) = \sum_i V^*(A \otimes P_i)V$ , where  $\{P_i\}$  is a POVM. This gives an identification between quantum channels of this form and POVMs.

**Definition 2.22** An **instrument** is a set of CP maps  $\{T_i\}$  whose sum is trace-preserving.

TODO: insert diagram.

**Remark 2.23** Instruments encompass the notions of quantum channels and POVMs:

- We can assign a quantum channel  $T : \rho \mapsto \sum_i T_i(\rho)$ . (Measurement outcome ignored.)
- By contrast, POVMs ignore the quantum system:  $p_i = \text{tr}(T_i(\rho)) = \text{tr}(T_i(\rho)\mathbb{I}) = \text{tr}(\rho T_i^*(\mathbb{I})) =: \text{tr}(\rho M_i)$ :  $\{M_i\}$  is a POVM.

**Remark 2.24** Instruments can be viewed as a special case of quantum channels by assigning to them the quantum channel

$$\rho \mapsto \sum_i T_i(\rho) \otimes |i\rangle \langle i|,$$

where  $\{|i\rangle\}$  is an orthonormal basis.

**Proposition 2.25** (Quantum Steering) Let  $\rho \in B(\mathbb{H}_A)$  be a density operator with purification  $|\psi\rangle \in \mathbb{H}_A \otimes \mathbb{H}_B$ . Let  $\rho = \sum_i \lambda_i \rho_i$  be a convex combination. Then there is an instrument  $\{T_i\}$  with each  $T_i : B(\mathbb{H}_B) \rightarrow B(\mathbb{H}_B)$ , such that  $\lambda_i \rho_i = \text{tr}_B((\mathbb{I} \otimes T_i)(|\psi\rangle \langle \psi|))$ .

## 2.4. Description of open quantum many-body systems

Assume evolution is

$$\rho_{SE}(t) = \rho_S(t) \otimes \rho_E \xrightarrow{dt} \rho_{SE}(t+dt) = \rho_S(t+dt) \otimes \rho_E(t+dt) = \rho_S(t+dt) \otimes \rho_E$$

**Definition 2.26** A **quantum Markov semigroup** is a 1-parameter continuous semigroup  $\{T_t : t \geq 0\}$  of quantum channels (so each  $T_t : \mathbb{S}(\mathbb{H}) \rightarrow \mathbb{S}(\mathbb{H})$ ).

Note that  $T_0 = \mathbb{I}$  and  $T_s \circ T_t = T_{t+s}$ . We have

$$\frac{d}{dt}T_t = \mathcal{L} \circ T_t = T_t \circ \mathcal{L},$$

where  $\mathcal{L}$  is the infinitesimal generator of the semigroup, called the **Liouvillian** or **Lindbladian**. This equation is called the **master equation** or **Liouville equation**. This gives

$$T_t = e^{t\mathcal{L}}.$$

## 2.5. Separability criteria

**Notation 2.27** Let  $A(\mathbb{H})$  denote the set of bounded linear Hermitian operators on  $\mathbb{H}$ .

**Definition 2.28** The **covariance** (or **operator correlation**) of  $\rho$  between subsystems  $A$  and  $B$  is

$$\text{Cor}_\rho(A : B) = \sup_{\|M_A\|, \|M_B\| \leq 1} |\text{tr}(\rho M_A T_B) - \text{tr}(\rho M_A) \text{tr}(\rho M_B)|,$$

where  $M_A \in A(H_A)$ ,  $M_B \in A(H_B)$ , and  $\|\cdot\|$  is the standard operator norm.

**Example 2.29** If  $\rho$  is separable, then  $\text{Cor}_\rho(A : B)$  measures classical correlation. If  $\rho = \rho_A \otimes \rho_B$ , then  $\text{Cor}_\rho(A : B) = 0$ .

**Definition 2.30** Let  $|\psi\rangle = \sum_{i=1}^d \sqrt{p_i} |e_i\rangle \otimes |f_i\rangle$  be the Schmidt decomposition of  $|\psi\rangle \in \mathbb{H}_A \otimes \mathbb{H}_B$ . Let  $\rho = |\psi\rangle\langle\psi|$ . The **entanglement entropy** of  $\rho$  is the Shannon entropy of the probability distribution  $(p_1, \dots, p_d)$ :

$$S_{\text{ENT}}(\rho) := - \sum_{i=1}^d p_i \log(p_i).$$

### Proposition 2.31

- $S_{\text{ENT}}(\rho) = 0$  iff the Schmidt rank of  $|\psi\rangle$  is 1.
- The maximum value of  $S_{\text{ENT}}(\rho)$  is  $\log(d)$ , and is achieved iff  $|\psi\rangle$  is maximally entangled, i.e.  $\lambda_i = 1/d$  for all  $i \in [d]$ .

**Proposition 2.32** (PPT Criterion) Let  $\rho \in \mathbb{S}(\mathbb{H}_A \otimes \mathbb{H}_B)$ . If  $\rho^{T_A}$  has a negative eigenvalue, then  $\rho$  is entangled.

*Proof (Hints).* Prove the contrapositive. □

*Proof.* Assume  $\rho$  is separable, so  $\rho = \sum_j p_j \rho_j^A \otimes \rho_j^B$ . Then

$$\rho^{T_A} = (\Theta \otimes \text{id})(\rho) = \sum_j p_j (\rho_j^A)^T \otimes \rho_j^B,$$

and so  $\rho^{T_A} \geq 0$ , as it is a sum of positive matrices. □

**Definition 2.33** Write  $S_{\text{SEP}} = \{\text{separable density matrices}\}$ , which is convex and compact. By the Hahn-Banach theorem, for all  $\rho \notin S_{\text{SEP}}$ , there exists a hyperplane determined by a Hermitian operator  $\omega$  such that  $\text{tr}(\rho\omega) < 0$  and  $\text{tr}(\sigma\omega) \geq 0$  for all  $\sigma \in S_{\text{SEP}}$ .  $\omega$  is called an **entanglement witness** for  $\rho$ .

By the Choi-Jamiolkowski isomorphism,  $\omega$  corresponds to a map  $\Lambda$  via the following:

$$\omega = (\Lambda \otimes \text{id}_B)(|\phi\rangle\langle\phi|).$$

**Remark 2.34** The entanglement witness corresponding to the transposition map is the flip operator  $F$ .

**Proposition 2.35** Let  $\mathbb{H}_{AB} = \mathbb{H}_A \otimes \mathbb{H}_B$  and let  $\rho \in \mathbb{S}(\mathbb{H}_{AB})$ . Then  $\rho$  is separable iff  $(\Lambda \otimes \text{id}_B)(\rho) \geq 0$  for every positive map  $\Lambda : B(\mathbb{H}_A) \rightarrow B(\mathbb{H}_A)$ .

*Proof (Hints).*

- $\Rightarrow$ : straightforward.
- $\Leftarrow$ : TODO.

□

*Proof.*  $\Rightarrow$ : let  $\rho$  be separable, so we can write  $\rho = \sum_j p_j \rho_j \otimes \sigma_j$ . Then for every positive  $\Lambda : B(\mathbb{H}_A) \rightarrow B(\mathbb{H}_A)$ ,

$$(\Lambda \otimes \text{id}_B)(\rho) = \sum_j \lambda_j \Lambda(\rho_j) \otimes \sigma_j \geq 0,$$

since each  $\Lambda(\rho_j) \geq 0$ .

$\Leftarrow$ : let  $\rho$  be entangled. We want to find a positive map  $\Lambda : B(\mathbb{H}_A) \rightarrow B(\mathbb{H}_A)$  such that  $(\Lambda \otimes \text{id}_B)(\rho)$  has a negative eigenvalue. By Definition 2.33,  $\rho$  has an entanglement witness  $\omega$ , with  $\text{tr}(\rho\omega) < 0$ . By the Choi-Jamiolkowski isomorphism, this defines a map  $\Lambda$  such that

$$\omega = (\Lambda^* \otimes \text{id}_B)(|\phi\rangle\langle\phi|).$$

Since  $\text{tr}(XY) = \text{tr}(\mathbb{F}(X \otimes Y))$ , and  $F = d|\phi\rangle\langle\phi|$ , we have for all  $A \in B(\mathbb{H}_A)$ ,  $B \in B(\mathbb{H}_B)$ ,

$$\begin{aligned} \text{tr}(B^T \Lambda(A)) &= \text{tr}(F(\Lambda(A) \otimes B^T)) \\ &= d \text{tr}((\Lambda \otimes \text{id}_B)(A \otimes B)(|\phi\rangle\langle\phi|)) \\ &= d \langle\phi|(\Lambda \otimes \text{id}_B)(A \otimes B)|\phi\rangle. \end{aligned}$$

TODO: finish.

□

**Remark 2.36**

- In the above proof, we use that  $\text{tr}(\rho\omega) = d \langle\phi|(\Lambda \otimes \text{id}_B)(\rho)|\phi\rangle < 0$  implies that  $(\Lambda \otimes \text{id}_B)$  has a negative eigenvalue. However, the converse is false. Hence, the positive map  $\Lambda$  corresponding to a witness  $\omega$  in fact “detects more entanglement” than  $\omega$ .
- It can be shown that  $\Lambda$  constructed from  $\omega$  detects an entangled state  $\rho$  iff  $\rho$  is detected by a witness of the form  $(\mathbb{I} \otimes \mathbb{X})\omega(\mathbb{I} \otimes X^*)$  for some  $X \in B(\mathbb{H}_B)$ .

**Remark 2.37** Note that Proposition 2.35 is a theoretical result but is not implementable (in a lab) since  $\Lambda$  is only required to be positive (but not CP). However, the map

$$T(\rho) = \frac{p}{d^2} \mathbb{I}_d \otimes \mathbb{I}_d + (1-p)(\Lambda \otimes \text{id}_B)(\rho)$$

is a CP map. If  $\rho$  is separable, then the minimal eigenvalue of  $T(\rho)$  must exceed a certain threshold. If it doesn't exceed this threshold, then  $\rho$  is entangled.

**Remark 2.38** Note that by using a change of abasis via a unitary  $U$ , we can obtain a different partial transpose  $\tilde{T}_A$  from the “usual” partial transpose  $T_A$ :

$$\rho^{\tilde{T}_A} = (U \otimes \mathbb{I})((U^* \otimes \mathbb{I})\rho(U \otimes \mathbb{I}))^{T_A}(U^* \otimes \mathbb{I}) = ((UU^T) \otimes \mathbb{I})\rho^{T_A}((UU^T)^* \otimes \mathbb{I}) \neq \rho^{T_A}.$$

Note that this non-uniqueness of the partial transpose does not affect the previous criteria, as they only deal with the eigenvalues, which are invariant under basis changes. Also, we have  $\rho^{\tilde{T}_A} \iff \rho^{T_A} \geq 0 \iff \rho^{T_B} \geq 0$ , since  $\rho^{T_A}$  and  $\rho^{T_B}$  differ only by a global transposition.

**Definition 2.39** A map  $\Lambda : \mathbb{B}(\mathbb{H}) \rightarrow \mathbb{B}(\mathbb{H})$  is called **decomposable** if  $\Lambda = \Lambda_1 + \Lambda_2 \circ \Theta$ , where  $\Lambda_1$  and  $\Lambda_2$  are positive maps and  $\Theta$  is a partial transpose. Otherwise, it is called **non-decomposable**.

**Example 2.40** The entanglement witness corresponding to a decomposable map  $\Lambda = \Lambda_1 + \Lambda_2 \circ \Theta$  is  $\omega = Q_1 + Q_2^T$ , where  $Q_i = d(\Lambda_i \otimes \mathbb{I})(|\phi\rangle\langle\phi|)$  is the entanglement witness of  $\Lambda_i$

**Proposition 2.41** (Reduction Criterion) Let  $\Lambda_{\text{red}}(A) = \text{tr}(A)\mathbb{I} - A$ . Note that  $\Lambda_{\text{red}}$  is positive. Proposition [2.35](#) gives us

$$(\Lambda_{\text{red}} \otimes \mathbb{I})(\rho) \implies \begin{cases} \rho_A \otimes \mathbb{I}_B \geq \rho_{AB} \\ \mathbb{I}_A \otimes \rho_B \geq \rho_{AB}. \end{cases}$$

The entanglement witness corresponding to  $\Lambda_{\text{red}}$  is  $(\mathbb{I} - F)^{T_A} = 2P_-^{T_A}$ , where  $P_-$  is the projector onto the anti-symmetric subspace (the space of anti-Hermitian operators). In this case, we obtain

$$\text{tr}(\rho\omega) < 0 \quad \text{iff} \quad \langle\phi|\rho|\phi\rangle \leq \frac{1}{d},$$

where  $|\phi\rangle$  is the maximally entangled state.

*Proof.* Omitted. □

**Remark 2.42** If  $\mathbb{H} = \mathbb{C}^2 \otimes \mathbb{C}^2$ ,  $P_-^{T_A}$  is 1-dimensional, which gives that entanglement being detected by  $\omega$  is equivalent to the PPT criterion.

**Proposition 2.43** Entangled states with positive partial transpose exist iff there are non-decomposable maps. Specifically, there exists a non-decomposable map  $T : B(\mathbb{H}_A) \rightarrow B(\mathbb{H}_B)$  iff there exists an entangled state  $\rho \in B(\mathbb{H}_A) \otimes B(\mathbb{H}_B)$  with positive partial transpose  $\rho^{T_A} \geq 0$ .

*Proof.* Omitted. □

**Proposition 2.44** Let  $\rho \in S(\mathbb{C}^2 \otimes \mathbb{C}^3)$  or  $S(\mathbb{C}^2 \otimes \mathbb{C}^2)$ . Then  $\rho$  is separable iff  $\rho^{T_A} \geq 0$ .

*Proof (Hints).* Use the fact that every positive  $\Lambda$  on a Hilbert space of dimension  $2 \otimes 2$  or  $2 \otimes 3$  is decomposable.  $\square$

*Proof.* This follows from the [PPT Criterion](#) and Proposition [2.43](#) combined with the fact that every positive  $\Lambda$  on a Hilbert space of dimension  $2 \otimes 2$  or  $2 \otimes 3$  is decomposable.  $\square$

### 3. Quantum hypothesis testing

The goal of quantum hypothesis testing is to distinguish between quantum states by using measurements. Given quantum states, the goal is to minimise the errors in distinguishing them. There are two main frameworks:

- Binary/simple hypothesis testing: we have a null hypothesis  $\rho_0$  and an alternative hypothesis  $\rho_1$ . The focus is on minimising either the Type I error (false positive) for a given bound on the Type II error (false negative), or vice versa.
- Quantum state discrimination: states are given with prior probabilities, and the goal is to maximise the probability of correct identification.

#### 3.1. Quantum state discrimination

Given an ensemble  $\{\rho_1, \dots, \rho_n\} \subseteq \mathbb{S}(\mathbb{H})$  of density operators with corresponding probabilities  $\{p_1, \dots, p_n\}$ , where  $p_i \geq 0$  and  $\sum_{i=1}^n p_i = 1$ . This can be interpreted as a set of  $n$  hypotheses (the  $\rho_i$ ) with corresponding a priori probability  $p_i$ . The goal is to maximise the average probability of correct identification of the hypothesis. To discriminate among the hypothesis, we use a POVM  $M = \{M_1, \dots, M_n\}$ , and we want to maximise

$$\mathcal{P}(M) := \sum_{j=1}^n \text{tr}(M_j p_j \rho_j) = \sum_{j=1}^n p_j \text{tr}(M_j \rho_j).$$

Note that the interpretation is as follows: we have an unknown quantum state  $\rho$  which is distributed over  $\mathbb{S}(\mathbb{H})$ , where  $\rho = \rho_i$  with probability  $p_i$ . Given that  $\rho = \rho_i$ , the probability of the measurement  $M$  yielding the (correct) outcome  $i$  is  $\text{tr}(M_i \rho_i)$ . So  $\mathcal{P}(M)$  is the expected value of the probability of measuring the correct outcome.

**Notation 3.1** Write  $\mathcal{M} = \text{span}\{(M_1, \dots, M_n) \in \mathbb{B}(\mathbb{H})^n, M_i \geq 0, \sum_i M_i = \mathbb{I}\}$  for the span of the set of POVMs with  $n$  operators, and write  $\mathcal{P}(\mathcal{M}) = \sup_{M \in \mathcal{M}} \mathcal{P}(M)$ .

**Notation 3.2** Write  $\sigma_i = p_i \rho_i$ .

**Notation 3.3** For any POVM  $M$ , write  $L = \sum_{i=1}^n M_i p_i \rho_i$ , so that  $\mathcal{P}(M) = \text{tr}(L)$ .

**Definition 3.4** A **maximum likelihood measurement** (or **optimal measurement**) is a measurement (POVM) that achieves the supremum (i.e. the optimal probability) in  $\mathcal{P}(\mathcal{M})$ .

**Proposition 3.5** The supremum in  $\mathcal{P}(\mathcal{M})$  is always attained, i.e. there is a measurement  $M^*$  such that  $\mathcal{P}(\mathcal{M}) = \mathcal{P}(M^*)$ .

*Proof (Hints).* Explain why  $\mathcal{M}$  is compact, the rest is straightforward.  $\square$

*Proof.* For each  $M \in \mathcal{M}$ , each  $M_i \geq 0$ , and  $\sum_i M_i = \mathbb{I}$ , which says that  $\mathcal{M}$  is compact. Also, the map  $M \mapsto \sum_{i=1}^n \text{tr}(M_i p_i \rho_i)$  is linear (and bounded), so is continuous, and so achieves its supremum on  $\mathcal{M}$ .  $\square$

**Remark 3.6** Note that since also for each  $M \in \mathcal{M}$ , each  $M_i \geq 0$ , we have that  $\mathcal{M}$  is convex.

**Theorem 3.7** Let  $\{\rho_1, \dots, \rho_n\}$  be an ensemble with probabilities  $\{p_1, \dots, p_n\}$ . For  $M = \{M_1, \dots, M_n\}$  and  $L = \sum_{i=1}^n M_i p_i \rho_i$ , TFAE:

1.  $M$  is an optimal measurement, i.e.  $\mathcal{P}(M) = \mathcal{P}(\mathcal{M})$ .
2. For all  $i \in [n]$ ,  $\frac{1}{2}(L + L^*) \geq p_i \rho_i$ .
3. For all  $i \in [n]$ ,  $L \geq p_i \rho_i$ .
4. There exists  $K \in \mathbb{B}(\mathbb{H})$  such that for all  $i \in [n]$ ,  $K \geq p_i \rho_i$  and  $(K - p_i \rho_i)M_i = 0$ .
5.  $\mathcal{P}(M) = \min\{\text{tr}(A) : A \in \mathcal{A}\}$ , where  $\mathcal{A} = \{A \in \mathbb{B}(\mathbb{H}) : A \geq p_i \rho_i \forall i\}$ .

**Remark 3.8**

- The inequalities in 3. and 4. of Theorem 3.7 imply that  $L$  and  $K$  are Hermitian.
- $L = K$  and are equal to a minimiser in 5. of Theorem 3.7.
- The uniqueness of  $K$  does not necessarily imply uniqueness of the optimal measurement.

*Proof (Hints).*

- $1 \Rightarrow 2$ : assume the opposite, let  $P$  be the orthogonal projector onto the negative eigenspace of  $L + L^* - 2p_i \rho_i$ . For fixed  $\varepsilon > 0$ , define  $M'_j = (\mathbb{I} - \varepsilon P)M_j(\mathbb{I} - \varepsilon P) + \varepsilon(2 - \varepsilon)P\delta_{ij}$ . Verify that  $M'$  is a POVM and that

$$\mathcal{P}(M') = \mathcal{P}(M) + \varepsilon \text{tr}(P(2p_i \rho_i - L - L^*)) - \varepsilon^2 \text{tr}(p_i \rho_i P) + \varepsilon^2 \sum_{j=1}^n \text{tr}(PM_j P p_j \rho_j).$$

- $3 \Rightarrow 1$ : for any POVM  $M' = \{M'_1, \dots, M'_n\}$ , show that  $\mathcal{P}(M) - \mathcal{P}(M') \geq 0$  (recall the properties of a POVM).
- $2 \Rightarrow 1$ : use simple modification of the  $3 \Rightarrow 1$  proof.
- $2 \Rightarrow 3$ : use that

$$\sum_{j=1}^n \text{tr}\left(\left(\frac{1}{2}(L + L^*) - p_j \rho_j\right)M_j\right) = \text{tr}\left(\frac{1}{2}(L + L^*) - L\right) = 0$$

- $3 \Rightarrow 4$ : straightforward.
- $4 \Rightarrow 1$ : show that  $\text{tr}(L) = \mathcal{P}(M)$ , show that  $\mathcal{P}(M) - \mathcal{P}(M') \geq 0$  for any POVM  $M' = \{M'_1, \dots, M'_n\}$ .
- $4 \Rightarrow 5$ : show that  $\mathcal{P}(M) = \text{tr}(K)$ .
- $5 \Rightarrow 4$ : should be straightforward by now.

$\square$

*Proof.*

- $1. \Rightarrow 2.$ : assume the opposite, i.e. that there exists  $i \in [n]$  such that  $\frac{1}{2}(L + L^*) \not\geq p_i \rho_i$ , i.e.  $L + L^* - 2p_i \rho_i$  is not positive semi-definite. Let  $P$  be the orthogonal projector

onto the negative eigenspace of  $L + L^* - 2p_i\rho_i$ . In particular,  $P$  is non-zero. Fix  $\varepsilon \in [0, 2]$  and define

$$M'_j = (\mathbb{I} - \varepsilon P)M_j(\mathbb{I} - \varepsilon P) + \varepsilon(2 - \varepsilon)P\delta_{ij}.$$

It is straightforward to check that  $M'$  is a POVM and that

$$\mathcal{P}(M') = \mathcal{P}(M) + \varepsilon \operatorname{tr}(P(2p_i\rho_i - L - L^*)) - \varepsilon^2 \operatorname{tr}(p_i\rho_i P) + \varepsilon^2 \sum_{j=1}^n \operatorname{tr}(PM_j P p_j \rho_j)$$

By construction,  $\operatorname{tr}(P(2p_i\rho_i - L - L^*)) \geq 0$ . Since the last two terms are  $O(\varepsilon^2)$ , for  $\varepsilon$  small enough,  $\mathcal{P}(M') > \mathcal{P}(M)$ , which contradicts our assumption that  $\mathcal{P}(M) = \mathcal{P}(\mathcal{M})$ .

- $3 \Rightarrow 1$  and  $2 \Rightarrow 1$ : let  $M'$  be another POVM. Since  $\mathcal{P}(M) = \operatorname{tr}(L)$ , we have

$$\begin{aligned} \mathcal{P}(M) - \mathcal{P}(M') &= \operatorname{tr}(L) - \sum_{j=1}^n \operatorname{tr}(M'_j p_j \rho_j) \\ &= \operatorname{tr}\left(L \sum_{j=1}^n M'_j\right) - \sum_{j=1}^n \operatorname{tr}(M'_j p_j \rho_j) \\ &= \sum_{j=1}^n \operatorname{tr}(M'_j (L - p_j \rho_j)) \end{aligned}$$

By 3,  $L \geq p_j \rho_j$ , hence  $\mathcal{P}(M) - \mathcal{P}(M') \geq 0$ . For  $2 \Rightarrow 1$ , since  $\operatorname{tr}(L) = \operatorname{tr}(L^*)$ , we can replace  $L$  in the above proof by  $\frac{1}{2}(L + L^*)$ .

- $2 \Rightarrow 3$ : using that  $\operatorname{tr}(L) = \operatorname{tr}(L^*)$ , we have

$$\sum_{j=1}^n \operatorname{tr}\left(\left(\frac{1}{2}(L + L^*) - p_j \rho_j\right)M_j\right) = \operatorname{tr}\left(\frac{1}{2}(L + L^*) - L\right) = 0$$

Since  $\frac{1}{2}(L + L^*) \geq p_j \rho_j$ , all the terms  $\frac{1}{2}(L + L^*) - p_j \rho_j$  are positive, so  $(\frac{1}{2}(L + L^*) - p_j \rho_j)M_j = 0$  since the sums of the traces are 0. Summing over  $j$  gives  $\frac{1}{2}(L + L^*) = L$ , so  $L$  is Hermitian.

- $3 \Rightarrow 4$ : choosing  $K = L$ , it is straightforward to check the conditions are satisfied.
- $4 \Rightarrow 1$ : since  $KM_j = p_j \rho_j M_j$  for all  $j$ , it is straightforward to show that  $\mathcal{P}(M) = \operatorname{tr}(L) = \operatorname{tr}(K)$  by summing over  $j$  and taking the trace. Letting  $M'$  be another POVM, we have

$$\begin{aligned} \mathcal{P}(M) - \mathcal{P}(M') &= \sum_{j=1}^n \operatorname{tr}(KM'_j) - \operatorname{tr}(p_j \rho_j M'_j) \\ &= \sum_{j=1}^n \operatorname{tr}((K - p_j \rho_j)M'_j) \geq 0 \end{aligned}$$

since  $K - p_j \rho_j \geq 0$ .

- $4 \Rightarrow 5$ : it is straightforward to show that

$$\mathcal{P}(M) = \operatorname{tr}(K).$$

We have  $K \in \mathcal{A}$  and for all  $A \in \mathcal{A}$ ,

$$\mathrm{tr}(K) = \sum_{j=1}^n \mathrm{tr}(KM_j) = \sum_{j=1}^n \mathrm{tr}(p_j \rho_j M_j) \leq \sum_{j=1}^n \mathrm{tr}(AM_j) = \mathrm{tr}(A)$$

So  $\mathcal{P}(M) = \mathrm{tr}(K) = \min\{\mathrm{tr}(A) : A \in \mathcal{A}\}$ . The argument in reverse shows the converse.

- 5  $\Rightarrow$  4: let  $A \in \mathcal{A}$  be such that  $\mathrm{tr}(A) = \mathcal{P}(M) = \mathrm{tr}(L)$ . Then

$$0 = \mathrm{tr}(A - L) = \mathrm{tr}\left(A \sum_{i=1}^n M_i - L\right) = \sum_{i=1}^n \mathrm{tr}((A - p_i \rho_i) M_i)$$

Since  $A \geq p_i \rho_i$  for all  $i$ , each term on the RHS is  $\geq 0$ , and so  $\mathrm{tr}((A - p_i \rho_i) M_i) = 0$ , but  $(A - p_i \rho_i) M_i \geq 0$ , so we can take  $K = A$ .

□

**Example 3.9** Let  $\rho_1, \dots, \rho_n$  be pairwise commuting states, so there exists an orthonormal basis  $\{|i\rangle : i \in [n]\}$  in which they can be simultaneously diagonalised. Let  $K$  be the diagonal operator with diagonal entries  $\langle j|K|j\rangle = \max_i \langle j|p_i \rho_i|j\rangle$ . By construction,  $K$  has minimal trace among all operators  $A$  such that  $A \geq p_i \rho_i$  for all  $i$  (and  $K$  is such an operator). Thus, by point 5 of Theorem 3.7,

$$\mathcal{P}(\mathcal{M}) = \min\{\mathrm{tr}(A) : A \geq p_i \rho_i \forall i\} = \mathrm{tr}(K) = \sum_{j=1}^n \langle j|K|j\rangle = \sum_j \max_i \langle j|p_i \rho_i|j\rangle.$$

**Example 3.10** Let  $\rho_1, \dots, \rho_n$  be pure states, each with associated a priori probability  $1/n$ . For simplicity, assume that

$$\sum_{i=1}^n p_i \rho_i = \frac{\mathbb{I}_d}{d}$$

(with  $d \leq n$ ). Define  $M_i = \frac{d}{n} \rho_i$  for each  $i \in [n]$ .  $\{M_i\}_{i=1}^n$  is a POVM which describes a maximum likelihood measurement. Since the  $\rho_i$  are pure states,  $\rho_i^2 = \rho_i$ , so for  $L = \sum_{i=1}^n M_i p_i \rho_i$ , we have

$$L = \sum_{i=1}^n M_i p_i \rho_i = \frac{d}{n} \sum_{i=1}^n p_i \rho_i^2 = \frac{d}{n} \sum_{i=1}^n p_i \rho_i = \frac{\mathbb{I}}{n} \geq p_i \rho_i$$

for all  $i$ . Hence,  $M$  is an optimal measurement by point 3 of Theorem 3.7.

### 3.2. Binary hypothesis testing

Let  $\rho_1$  and  $\rho_2$  be density matrices with a priori probability  $p$  and  $1 - p$ . Consider the POVM  $M = (M_1, M_2) = (\mathbb{I}, \mathbb{I} - P)$  with  $P$  an orthogonal projection. Assigning  $P$  to  $\rho_1$  and  $\mathbb{I} - P$  to  $\rho_2$ , the probability of error is

$$\mathcal{E}(M) := p \mathrm{tr}(\rho_1(\mathbb{I} - P)) + (1 - p) \mathrm{tr}(\rho_2 P).$$

Also,

$$\mathcal{P}(M) = p \operatorname{tr}(\rho_1 P) + (1 - p) \operatorname{tr}(\rho_2(\mathbb{I} - P))$$

Note that  $\mathcal{P}(M) + \mathcal{E}(M) = 1$ .

**Definition 3.11** Let  $\mathbb{H}$  be a finite dimensional Hilbert space. For  $p \in [1, \infty)$ , the **Schatten  $p$ -norm** is defined as

$$\begin{aligned} \|\cdot\|_p : \mathbb{B}(\mathbb{H}) &\rightarrow [0, \infty), \\ \|A\| &= \operatorname{tr}(|A|^p)^{1/p}. \end{aligned}$$

We can also define  $\|A\|_\infty = \lim_{p \rightarrow \infty} \|A\|_p = \max_i \{|\lambda_i|\}$ , where  $\lambda_i$  are the eigenvalues of  $A$ .

**Theorem 3.12** (Quantum Neyman-Pearson) We have

$$\mathcal{E}(M) \geq \frac{1}{2} \left( 1 - \|p\rho_1 - (1-p)\rho_2\|_1 \right)$$

with equality iff  $P$  is a projection onto  $(p\rho_1 - (1-p)\rho_2)_+$ , the positive eigensubspace of  $p\rho_1 - (1-p)\rho_2$ .

*Proof (Hints).*

- Let  $A = p\rho_1 - (1-p)\rho_2$ . By considering the positive and negative parts  $A_+$  and  $A_-$  of  $A$ , show that  $\operatorname{tr}(A_+) = \frac{1}{2}(\|A\|_1 + \operatorname{tr}(A))$ .
- Also show that  $\mathcal{E}(M) = p - \operatorname{tr}(PA)$ , and explain why the minimum (over  $P$ ) of this is attained iff  $PA_+ = A_+$  and  $PA_- = 0$ .

□

*Proof.* For every Hermitian  $A$ , we can write  $A = A_+ + A_-$ , where  $A_+$  is the positive part and  $A_-$  is the negative part. We have

$$\operatorname{tr}(A_+) = \frac{1}{2}(\|A\|_1 + \operatorname{tr}(A))$$

since  $\|A\|_1 = \operatorname{tr}(|A|) = \operatorname{tr}(A_+ - A_-)$  and  $\operatorname{tr}(A) = \operatorname{tr}(A_+ + A_-)$ . Now

$$\begin{aligned} \mathcal{E}(M) &= p \operatorname{tr}(\rho_1(\mathbb{I} - P)) + (1 - p) \operatorname{tr}(\rho_2 P) \\ &= p - p \operatorname{tr}(\rho_1 P) + (1 - p) \operatorname{tr}(\rho_2 P) \\ &= p - \operatorname{tr}(P(p\rho_1 - (1-p)\rho_2)) =: p - \operatorname{tr}(PA) \end{aligned}$$

So maximum of above is attained iff  $PA_+ = A_+$  and  $PA_- = 0$ , i.e.  $P$  is an orthonormal projection onto  $A_+$ . Hence,

$$\begin{aligned} \min_M \mathcal{E}(M) &= p - \operatorname{tr}((p\rho_1 - (1-p)\rho_2)_+) \\ &= p - \frac{1}{2}(\|p\rho_1 - (1-p)\rho_2\|_1 + \operatorname{tr}(p\rho_1 - (1-p)\rho_2)) \\ &= \frac{1}{2} \left( 1 - \|p\rho_1 - (1-p)\rho_2\|_1 \right) \end{aligned}$$

Alternatively, we could define  $L = Pp\rho_1 + (\mathbb{I} - P)(1 - p)\rho_2$  which satisfies  $L \geq p\rho_1$  and  $L \geq (1 - p)\rho_2$ , hence is an optimal measurement, hence  $1 = \mathcal{P}(M) + \mathcal{E}(M) \leq \text{tr}(L) + \mathcal{E}(M)$ .  $\square$

Now assume we have  $m$  copies of  $\rho_1$  and  $\rho_2$ , and we can treat them as single density matrices:  $\rho_1^{\otimes m}$  and  $\rho_2^{\otimes m}$ . For the optimal measurement, the error rate is

$$\mathcal{E}_m^{\text{opt}} = \frac{1}{2} \left( 1 - \|p\rho_1^{\otimes m} - (1 - p)\rho_2^{\otimes m}\|_1 \right)$$

It can be shown that  $\mathcal{E}_m^{\text{opt}}$  decays exponentially with  $m$ , i.e.  $\mathcal{E}_m^{\text{opt}} \leq Ke^{-\xi m}$ ,  $K, \xi > 0$ . Note that this upper bound is independent of  $p$ .

**Lemma 3.13** If  $A, B \in \mathbb{B}(\mathbb{H})$  are positive, then  $\forall s \in [0, 1]$ ,  $\text{tr}((A^s - B^s)A^{1-s}) \leq \text{tr}((A - B)_+)$ .

*Proof.* Consequence of operator monotonicity of  $z \mapsto z^s$  for all  $s \in [0, 1]$  (details omitted).  $\square$

**Theorem 3.14** (Quantum Chernoff Bound) Let  $p \neq 0, 1$ . Then

$$\xi := \lim_{m \rightarrow \infty} \left( -\frac{1}{m} \log(\mathcal{E}_m^{\text{opt}}) \right) = -\log \left( \inf_{s \in [0, 1]} \text{tr}(\rho_1^{1-s} \rho_2^s) \right)$$

*Proof (Hints).*

- Show that  $\frac{1}{2}(\text{tr}(A + B) - \|A - B\|_1) \leq \text{tr}(B^s A^{1-s})$  for positive  $A, B \in \mathbb{B}(\mathbb{H})$  and  $s \in [0, 1]$ .
- Now take  $A = p\rho_1^{\otimes m}$  and  $B = (1 - p)\rho_2^{\otimes m}$  to show inequality in the theorem statement.
- To show equality, consider

$$\begin{aligned} \hat{\rho}_1 &= \sum_{j,k} \lambda_j^{(1)} \left| \langle \psi_j^{(1)} | \psi_k^{(2)} \rangle \right| |jk\rangle \langle jk| \\ \hat{\rho}_2 &= \sum_{j,k} \lambda_j^{(2)} \left| \langle \psi_j^{(1)} | \psi_k^{(2)} \rangle \right| |jk\rangle \langle jk|, \end{aligned}$$

where  $\rho_i = \sum_j \lambda_j^{(i)} |\psi_j^{(i)}\rangle \langle \psi_j^{(i)}|$ , and use that equality is achieved when applied to commuting operators.  $\square$

*Proof.* By Lemma 3.13,

$$\begin{aligned} \frac{1}{2}(\text{tr}(A + B) - \|A - B\|_1) &= \frac{1}{2}(2 \text{tr}(A) - \text{tr}(A - B) - \text{tr}((A - B)_+) + \text{tr}((A - B)_-)) \\ &= \text{tr}(A) - \text{tr}((A - B)_+) \\ &\leq \text{tr}(A) - \text{tr}((A^s - B^s)A^{1-s}) = \text{tr}(B^s A^{1-s}) \end{aligned}$$

Let  $A = p\rho_1^{\otimes m}$  and  $B = (1 - p)\rho_2^{\otimes m}$ . Then by above and [Quantum Neyman-Pearson](#),

$$\mathcal{E}_m^{\text{opt}} = \frac{1}{2} \left( 1 - \|p\rho_1^{\otimes m} - (1-p)\rho_2^{\otimes m}\|_1 \right) \leq (1-p)^s p^{1-s} \text{tr}(\rho_1^{1-s} \rho_2^s)^m$$

Hence

$$\mathcal{E}_m^{\text{opt}} \leq \inf_{s \in [0,1]} p^{1-s} (1-p)^s \text{tr}(\rho_1^{1-s} \rho_2^s)^m \leq \inf_{s \in [0,1]} \text{tr}(\rho_1^{1-s} \rho_2^s)^m$$

so

$$-\frac{1}{m} \log \mathcal{E}_m^{\text{opt}} \geq -\log \inf_{s \in [0,1]} \text{tr}(\rho_1^{1-s} \rho_2^s)$$

And we can take the limit  $m \rightarrow \infty$ .

To show equality: given  $\rho_1, \rho_2$  we can construct  $\hat{\rho}_1, \hat{\rho}_2$  such that  $[\hat{\rho}_1, \hat{\rho}_2] = 0$  and  $\text{tr}(\hat{\rho}_1^{1-s} \hat{\rho}_2^s) = \text{tr}(\rho_1^{1-s} \rho_2^s)$ : explicitly, let  $\rho_i = \sum_j \lambda_j^{(i)} |\psi_j^{(i)}\rangle \langle \psi_j^{(i)}|$ , then we define

$$\begin{aligned} \hat{\rho}_1 &= \sum_{j,k} \lambda_j^1 \left| \langle \psi_j^{(1)} | \psi_k^{(2)} \rangle \right| |jk\rangle \langle jk| \\ \hat{\rho}_2 &= \sum_{j,k} \lambda_j^2 \left| \langle \psi_j^{(1)} | \psi_k^{(2)} \rangle \right| |jk\rangle \langle jk|, \end{aligned}$$

where  $\{|ij\rangle\}$  is an orthonormal basis of  $\mathbb{H} \otimes \mathbb{H}$ .  $\hat{\rho}_1, \hat{\rho}_2$  achieve equality in the above inequality.  $\square$

### 3.3. The pretty good measurement

**Definition 3.15** Given a collection of states  $\{\rho_i\}_{i=1}^n$  with associated prior probability  $\{p_i\}_{i=1}^n$ , the **pretty good measurement** is  $M^P = \{M_i^P\}_{i=1}^n$ , where

$$\begin{aligned} M_i^P &= R^{-1/2} p_i \rho_i R^{-1/2} + \frac{1}{n} (\mathbb{I} - R^{-1/2} R R^{-1/2}) = R^{-1/2} p_i \rho_i R^{-1/2} + \frac{1}{n} \mathbb{I}_{\{\ker R\}} \\ R &= \sum_{i=1}^n p_i \rho_i, \end{aligned}$$

where  $R^{-1}$  is the Moore-Penrose pseudo-inverse.

**Definition 3.16** Given a collection of states  $\{\rho_i\}_{i=1}^n$  with associated prior probability  $\{p_i\}_{i=1}^n$ , the **square measurement** is  $M^S = \{M_i^S\}_{i=1}^n$ , where

$$\begin{aligned} M_i^S &= S^{-1/2} p_i^2 \rho_i^2 S^{-1/2} + \frac{1}{n} (\mathbb{I} - S^{-1/2} S S^{-1/2}), \\ S &= \sum_{i=1}^n p_i^2 \rho_i^2. \end{aligned}$$

**Theorem 3.17** (Holder's Inequality) For  $p, q \in [1, \infty]$  and  $\frac{1}{p} + \frac{1}{q} = 1$ , we have

$$\|AB\|_1 = \text{tr}(|AB|) \leq \|A\|_p \|B\|_q.$$

**Definition 3.18** Let  $I$  be an interval.  $f : I \rightarrow \mathbb{R}$  is **operator convex** on  $I$  if

$$f(\lambda A + (1 - \lambda)B) \leq \lambda f(A) + (1 - \lambda)f(B),$$

for all  $A, B$  Hermitian with spectra in  $I$  and all  $\lambda \in [0, 1]$ .

**Theorem 3.19** (Jensen's Inequality) Let  $f$  be continuous on an interval  $I$ . TFAE:

- $f$  is operator convex on  $I$ .
- For each  $n \in \mathbb{N}$ ,

$$f\left(\sum_{i=1}^n A_i^* X_i A_i\right) \leq \sum_{i=1}^n A_i^* f(X_i) A_i,$$

for all  $X_1, \dots, X_n$  which are bounded self-adjoint operators whose spectra are contained in  $I$  and all operators  $A_1, \dots, A_n$  are operators which satisfy  $\sum_{i=1}^n A_i^* A_i = \mathbb{I}$ .

- $f(V^* X V) \leq V^* f(X) V$  for all Hermitian  $X$  with spectrum in  $I$  and all isometries  $V$ .

**Proposition 3.20** We have

$$\text{tr}(S^{1/2})^2 \leq \mathcal{P}(M^S) \leq \mathcal{P}_{\text{opt}} \leq \text{tr}(S^{1/2}).$$

*Proof (Hints).*

- For simplicity, assume  $S$  is invertible. For first inequality, write  $S^{1/2} = S S^{-1/2}$ , use cyclicity to introduce  $\sigma_i^{1/2}$  where appropriate, then use [Jensen's Inequality](#).
- For third inequality, explain why  $\sigma_i \leq S^{1/2}$  for each  $i$ , and use that for any POVM  $M$ ,  $A \mapsto \text{tr}(M_i A)$  is an operator monotone.

□

*Proof.* For simplicity, assume  $S$  is invertible. The second inequality follows by definition. For the first, we have (letting  $\sigma_i = p_i \rho_i$ )

$$\begin{aligned} \text{tr}(S^{1/2})^2 &= \text{tr}(S S^{-1/2})^2 = \text{tr}\left(\sum_{i=1}^n p_i^2 \rho_i^2 S^{-1/2}\right)^2 \\ &= \left(\sum_{i=1}^n \text{tr}\left(\sigma_i(\sigma_i^{1/2} S^{-1/2} \sigma_i^{1/2})\right)\right)^2 \quad \text{by cyclicity} \\ &\leq \sum_{i=1}^n \text{tr}\left(\sigma_i(\sigma_i^{1/2} S^{-1/2} \sigma_i^{1/2})^2\right) \quad \text{by [Jensen's Inequality](#)} \\ &= \sum_{i=1}^n \text{tr}(\sigma_i^2 S^{-1/2} \sigma_i S^{-1/2}) \quad \text{by cyclicity} \\ &= \sum_{i=1}^n \text{tr}(\sigma_i M_i^S) \quad \text{by cyclicity} \\ &= \mathcal{P}(M^S). \end{aligned}$$

For the third inequality, note that  $\sigma_i^2 \leq \sum_j \sigma_j^2 = S$  for each  $i$ , since the  $\sigma_i$  are positive semi-definite. Since  $z \mapsto z^{1/2}$  is operator monotone, we have  $\sigma_i \leq S^{1/2}$  for each  $i \in [n]$ .

Also, for any POVM  $M = \{M_i\}$ ,  $A \mapsto \text{tr}(M_i A)$  is operator monotone, hence  $\text{tr}(M_i \sigma_i) \leq \text{tr}(M_i S^{1/2})$ . Summing over  $i$ , we obtain

$$\sum_i \text{tr}(M_i \sigma_i) \leq \sum_i \text{tr}(M_i S^{1/2}) = \text{tr}\left(\left(\sum_i M_i\right) S^{1/2}\right) = \text{tr}(\mathbb{I} \cdot S^{1/2}) = \text{tr}(S^{1/2}).$$

□

**Proposition 3.21** We have

$$(\mathcal{P}_{\text{opt}})^2 \leq \mathcal{P}(M^P) \leq \mathcal{P}_{\text{opt}}.$$

*Proof (Hints).* For simplicity, assume  $R$  is invertible. For the first inequality, show that for any POVM  $M$ ,  $\left(\sum_{i=1}^n \text{tr}(M_i \sigma_i)\right)^2 \leq \mathcal{P}(M^P)$ , using cyclicity to introduce  $R^{1/4}$  and  $R^{-1/4}$  where appropriate, [Holder's Inequality](#), Cauchy-Schwarz, the fact that  $\|M_i\|_\infty \leq 1$ . Use the fact that  $ABA \geq 0$  if  $A, B \geq 0$ . □

*Proof.* For simplicity, assume  $R$  is invertible. The second inequality follows from the definition. For the first, let  $M = \{M_i\}_{i=1}^n$  be a POVM. Then

$$\begin{aligned} \left(\sum_{i=1}^n \text{tr}(M_i \sigma_i)\right)^2 &= \left(\sum_{i=1}^n \text{tr}((R^{1/4} M_i R^{1/4}) \cdot (R^{-1/4} \sigma_i R^{-1/4}))\right)^2 \\ &\leq \left(\sum_{i=1}^n \|R^{1/4} M_i R^{1/4}\|_2 \|R^{-1/4} \sigma_i R^{-1/4}\|_2\right)^2 \quad \text{by Holder} \\ &\leq \sum_{i=1}^n \|R^{1/4} M_i R^{1/4}\|_2^2 \cdot \sum_{i=1}^n \|R^{-1/4} \sigma_i R^{-1/4}\|_2^2 \quad \text{by Cauchy-Schwarz} \end{aligned}$$

The first term in the final product is

$$\begin{aligned} \sum_{i=1}^n \|R^{1/4} M_i R^{1/4}\|_2^2 &= \sum_{i=1}^n \text{tr}((R^{1/4} M_i R^{1/4})^2) = \sum_{i=1}^n \text{tr}(R^{1/2} M_i R^{1/2} M_i) \\ &\leq \sum_{i=1}^n \text{tr}(R^{1/2} M_i R^{1/2}) = \text{tr}(R) = 1, \end{aligned}$$

where the inequality follows from [Holder's Inequality](#), since  $\|M_i\|_\infty \leq 1$ . (Note that  $R^{1/4} M_i R^{1/4}$  is PSD since  $M_i$  and  $R^{1/4}$  are, so can ignore absolute values.) The second term is

$$\sum_{i=1}^n \|R^{-1/4} \sigma_i R^{-1/4}\|_2^2 = \sum_{i=1}^n \text{tr}(M_i^P \sigma_i) = \mathcal{P}(M^P).$$

□

**Corollary 3.22** Since  $\mathcal{E}(M) = 1 - \mathcal{P}(M)$  and  $\mathcal{E}_{\text{opt}} = 1 - \mathcal{P}_{\text{opt}}$ , we have

$$(P_{\text{opt}})^2 \leq \mathcal{P}(M^P), \mathcal{P}(M^S) \leq \mathcal{P}_{\text{opt}}, \quad \text{and} \quad \mathcal{E}_{\text{opt}} \leq \mathcal{E}(M^P), \mathcal{E}(M^S) \leq 2\mathcal{E}_{\text{opt}}.$$

### 3.4. Asymmetric hypothesis testing

**Definition 3.23** Given  $m$  copies of states  $\rho$  and  $\sigma$  that we want to classify with a POVM  $(P_m, \mathbb{I} - P_m)$ , the **Type I error** is  $\alpha_m(P_m) = \text{tr}(\rho^{\otimes m}(\mathbb{I} - P_m))$ , and the **Type II error** is  $\beta_m(P_m) = \text{tr}(\sigma^{\otimes m} P_m)$ .

Note by the [Quantum Chernoff Bound](#), we have

$$\liminf_{m \rightarrow \infty} -\frac{1}{m} \log \alpha_m(P_m) \geq \xi, \quad \liminf_{m \rightarrow \infty} -\frac{1}{m} \log \beta_m(P_m) \geq \xi.$$

**Theorem 3.24** (Quantum Stein's Lemma) Let  $\rho, \sigma \in \mathbb{S}(\mathbb{H})$ ,  $\varepsilon \in (0, 1)$ , let  $\beta_m$  be minimised over all POVMs  $(P_m, \mathbb{I} - P_m)$  subject to  $\alpha_m(P_m) \leq \varepsilon$ . Then

$$\lim_{m \rightarrow \infty} -\frac{1}{m} \log \beta_m = D(\rho \parallel \sigma),$$

where  $D(\rho \parallel \sigma) = \text{tr}(\rho(\log \rho - \log \sigma))$  is the relative entropy between  $\rho$  and  $\sigma$ .

*Proof.* First we show that  $\lim_{m \rightarrow \infty} -\frac{1}{m} \log \beta_m \leq D(\rho \parallel \sigma)$ .

It can be shown that for  $A, B$  positive semi-definite,  $\text{tr}((A - B)_+) \leq \text{tr}(A^{1+s} B^{-s})$  for all  $s \in [0, 1]$ . Let  $A - B = \sum_i \mu_i Q_i$  be the spectral decomposition of  $A - B$ , and let  $J(X) = \sum_i Q_i X Q_i$  be the pinching on the eigenbasis of  $A - B$ . This satisfies  $[J(A), J(B)] = 0$ ; also,  $\text{tr}(A^{1+s} B^{-s})$  is non-increasing under CPTP maps (i.e.  $\text{tr}(\Phi(A)^{1+s} \Phi(B)^{-s}) \leq \text{tr}(A^{1+s} B^{-s})$  for all  $A, B$  positive semi-definite and quantum channels  $\Phi$ ). We also have  $\text{tr}((A - B)_+) = \text{tr}((T(A) - T(B))_+)$ . Combining these facts, we can assume WLOG that  $A$  and  $B$  are diagonal matrices. In this case, the inequality  $\text{tr}((A - B)_+) \leq \text{tr}(A^{1+s} B^{-s})$  is simply due to the fact that  $a - b \leq a(a/b)^s$  for all  $a, b > 0$ .

Take  $A = \rho^{\otimes m}$  and  $B = e^{\lambda m} \sigma^{\otimes m}$ , with  $\lambda$  a constant to be specified later. Then

$$\begin{aligned} \text{tr}((\rho^{\otimes m} - e^{\lambda m} \sigma^{\otimes m}) P_m) &\leq \text{tr}((\rho^{\otimes m})^{1+s} e^{-\lambda m s} (\sigma^{\otimes m})^{-s}) \\ &= e^{-\lambda m s} \text{tr}(\rho^{1+s} \sigma^{-s})^m \end{aligned}$$

Note that  $\alpha_m(P_m) \leq \varepsilon$  by assumption, i.e.  $1 - \varepsilon \leq \text{tr}(\rho^{\otimes m} P_m)$ . So by the above inequality,

$$\begin{aligned} (1 - \varepsilon) - e^{\lambda m} \beta_m(P_m) &\leq \text{tr}(\rho^{\otimes m} P_m) - e^{\lambda m} \text{tr}(\sigma^{\otimes m} P_m) \leq e^{-\lambda m s} \text{tr}(\rho^{1+s} \sigma^{-s})^m \\ &= e^{-\lambda m s} e^{m f(s)} = e^{m(-\lambda s + f(s))} \end{aligned}$$

where  $f(s) = \log \text{tr}(\rho^{1+s} \sigma^{-s})$ . So we have

$$\begin{aligned} 1 - \varepsilon - e^{\lambda m} \beta_m(P_m) &\leq e^{m(-\lambda s + f(s))} \leq e^{\lambda m} \beta_m(P_m) \\ \text{i.e. } \beta_m(P_m) &\geq e^{-\lambda m} ((1 - \varepsilon) - e^{m(f(s) - \lambda s)}) \end{aligned}$$

Clearly  $f(0) = 0$  and it can be shown that  $f'(0) = D(\rho \parallel \sigma)$ . So take  $\lambda = D(\rho \parallel \sigma) + \delta$  for any  $\delta > 0$ . Then  $\exists s \in (0, 1]$  such that  $\lambda s > f(s)$ , hence  $e^{m(f(s) - \lambda s)} < 1$  for all  $m \in \mathbb{N}$ . This gives

$$\begin{aligned}
\limsup_{m \rightarrow \infty} -\frac{1}{m} \log \beta_m(P_m) &\leq \limsup_{m \rightarrow \infty} -\frac{1}{m} \log(e^{-\lambda m}((1-\varepsilon) - e^{m(f(s)-\lambda s)})) \\
&= \limsup_{m \rightarrow \infty} \left( \lambda - \frac{1}{m} \log((1-\varepsilon) - e^{m(f(s)-\lambda s)}) \right) \\
&\leq \lambda \leq D(\rho \parallel \sigma) + \delta.
\end{aligned}$$

Since  $\delta > 0$  was arbitrary, this shows inequality.

For equality: let  $\sigma^{\otimes m} = \sum_{i=1}^k \lambda_i P_i$  be the spectral decomposition of  $\sigma^{\otimes m}$ . Define the completely positive linear map  $T : B(\mathbb{H}^{\otimes m}) \rightarrow B(\mathbb{H}^{\otimes m})$  by  $T(X) = \sum_{i=1}^k P_i X P_i$  (this is called a **pinching** on the eigenbasis of  $\sigma^{\otimes m}$ ). Now

$$\begin{aligned}
D(T(\rho^{\otimes m}) \parallel \sigma^{\otimes m}) &= D(T(\rho^{\otimes m}) \parallel T(\sigma^{\otimes m})) \leq D(\rho^{\otimes m} \parallel \sigma^{\otimes m}) \quad \text{by data-processing} \\
&= mD(\rho \parallel \sigma) \quad \text{by additivity} \\
&\leq D(T(\rho^{\otimes m}) \parallel \sigma^{\otimes m}) + d \log(m+1).
\end{aligned}$$

By the inequality, have  $D(\rho \parallel \sigma) = \lim_{m \rightarrow \infty} \frac{1}{m} D(T(\rho^{\otimes m}) \parallel \sigma^{\otimes m})$ . Also, since the pinching  $T$  satisfies  $[T(\rho^{\otimes m}), \sigma^{\otimes m}] = 0$ , the RHS is interpretable as a classical relative entropy, and classical Stein's lemma has equality.  $\square$

## 4. Distances and entropy measures

**Notation 4.1** In this section,  $\log$  denotes the base two logarithm.

### 4.1. Quantum entropies

**Definition 4.2** Let  $\rho \in \mathbb{S}(\mathbb{H})$  be a density matrix. The **von Neumann entropy** of  $\rho$  is given by

$$S(\rho) := -\text{tr}(\rho \log \rho).$$

#### Remark 4.3

- The von Neumann entropy extends the classical Shannon entropy of a discrete probability distribution  $\{p_i\}$ , given by  $-\sum_i p_i \log p_i$ . In particular, treating the eigenvalues  $\{\lambda_i\}$  of  $\rho$  as a distribution, it is easy to see that the von Neumann entropy of  $\rho$  is the Shannon entropy of the distribution  $\{\lambda_i\}$  (since if  $\rho = U D U^*$  for diagonal  $D$  and unitary  $U$ , then  $\log \rho = U \log(D) U^*$ , where  $\log(D)$  is computed entrywise).
- It quantifies the quantum information content per letter of ensemble (the minimum number of qubits per letter that are necessary to reliably encode a message).
- It also quantifies the amount of entanglement of a bipartite pure state.

**Proposition 4.4** Properties of von Neumann entropy: let  $\rho \in \mathbb{S}(\mathbb{H})$  with  $\dim \mathbb{H} = d$ , then

- If  $\rho = |\psi\rangle\langle\psi|$  is pure, then  $S(\rho) = 0$ .
- **Unitary invariance:**  $S(U\rho U^{-1}) = S(\rho)$  for every unitary  $U$ .
- $S(\rho) \leq \log d$ .
- **Concavity:** for  $p_i \geq 0$  and  $\sum_i p_i = 1$ , we have

$$S\left(\sum_i p_i \rho_i\right) \geq \sum_i p_i S(\rho_i)$$

- **Subadditivity:** for all  $\rho_{AB} \in \mathbb{S}(\mathbb{H}_A \otimes \mathbb{H}_B)$ , with  $\rho_A = \text{tr}_B(\rho_{AB})$  and  $\rho_B = \text{tr}_A(\rho_{AB})$ ,

$$S(\rho_{AB}) \leq S(\rho_A) + S(\rho_B).$$

- **Additivity:** for all  $\rho_{AB} = \rho_A \otimes \rho_B \in \mathbb{S}(\mathbb{H}_A \otimes \mathbb{H}_B)$ , we have

$$S(\rho_{AB}) = S(\rho_A) + S(\rho_B).$$

- **Strong subadditivity:** for all  $\rho_{ABC} \in \mathbb{S}(\mathbb{H}_A \otimes \mathbb{H}_B \otimes \mathbb{H}_C)$ ,

$$S(\rho_{ABC}) + S(\rho_B) \leq S(\rho_{AB}) + S(\rho_{BC})$$

- **Araki-Lieb inequality:** for all  $\rho_{AB} \in \mathbb{S}(\mathbb{H}_A \otimes \mathbb{H}_B)$ ,

$$S(\rho_{AB}) \geq |S(\rho_A) - S(\rho_B)|.$$

**Remark 4.5** If  $\rho_{AB}$  is pure, then  $S(\rho_{AB}) = 0$  by Proposition 4.4, and so by the Araki-Lieb inequality,  $S(\rho_A) = S(\rho_B)$ . However, in this case they don't have to be equal to 0.

**Corollary 4.6** Let  $\rho_{SE} = \rho_S \otimes \rho_E \in \mathbb{S}(\mathbb{H}_S \otimes \mathbb{H}_E)$ . Then by additivity,  $S(\rho_{SE}) = S(\rho_S) + S(\rho_E)$ . Consider the evolution

$$\rho_{SE} \mapsto U \rho_{SE} U^* = \rho'_{SE}.$$

Then by unitary invariance and subadditivity,

$$S(\rho_S) + S(\rho_E) = S(\rho_{SE}) = S(\rho'_{SE}) \leq S(\rho'_S) + S(\rho'_E).$$

This describes the second law of thermodynamics.

**Definition 4.7** Let  $\rho_{AB} \in \mathbb{S}(\mathbb{H}_A \otimes \mathbb{H}_B)$ ,  $\rho_A = \text{tr}_B(\rho_{AB})$ ,  $\rho_B = \text{tr}_A(\rho_{AB})$ . The **quantum mutual information** is

$$I_\rho(A : B) = S(\rho_A) + S(\rho_B) - S(\rho_{AB}).$$

By subadditivity of von Neumann entropy, this is always non-negative.

**Definition 4.8** Let  $\rho_{ABC} \in \mathbb{S}(\mathbb{H}_A \otimes \mathbb{H}_B \otimes \mathbb{H}_C)$ . The **conditional mutual information** is

$$I_\rho(A : C \mid B) := S(\rho_{AB}) + S(\rho_{BC}) - S(\rho_{ABC}) - S(\rho_B)$$

which is always non-negative by strong subadditivity of von Neumann entropy.

**Definition 4.9** For  $\rho_{AB} \in \mathbb{S}(\mathbb{H}_A \otimes \mathbb{H}_B)$ , the **conditional entropy** is

$$H(A \mid B)_\rho := S(\rho_{AB}) - S(\rho_B).$$

**Proposition 4.10**

- $H(A \mid B)_\rho \geq -\log(\dim \mathbb{H}_A)$ , so can be negative! This is different to the classical case.
- $S(\rho_A) \geq H(A \mid B)_\rho$ .

**Definition 4.11** The **quantum (Umegaki) relative entropy** of  $\rho, \sigma \in \mathbb{S}(\mathbb{H})$  is

$$D(\rho \parallel \sigma) := \begin{cases} \text{tr}(\rho(\log \rho - \log \sigma)) & \text{if } \ker \sigma \subseteq \ker \rho \\ \infty & \text{otherwise.} \end{cases}$$

It is a quantum analogue of the classical relative entropy (the Kullback-Leibler divergence).

**Definition 4.12** The **Belavkin-Staszewski relative entropy** of  $\rho, \sigma \in \mathbb{S}(\mathbb{H})$  is

$$\hat{D}(\rho \parallel \sigma) = \text{tr}(\rho \log(\rho^{1/2} \sigma^{-1} \rho^{1/2})).$$

**Proposition 4.13** We have  $D(\rho \parallel \sigma) \leq \hat{D}(\rho \parallel \sigma)$ , with equality iff  $[\rho, \sigma] = 0$ .

**Proposition 4.14** Properties of quantum relative entropy:

- $\rho \mapsto D(\rho \parallel \sigma)$  and  $\rho \mapsto \hat{D}(\rho \parallel \sigma)$  are continuous.
- **Non-negativity:**  $D(\rho \parallel \sigma) \geq 0$  with equality iff  $\rho = \sigma$ , and similarly for  $\hat{D}$ .
- **Unitary invariance:**  $D(U\rho U^* \parallel U\sigma U^*) = D(\rho \parallel \sigma)$ , and similarly for  $\hat{D}$ .
- **Additivity:**

$$D(\rho_A \otimes \rho_B \parallel \sigma_A \otimes \sigma_B) = D(\rho_A \parallel \sigma_A) + D(\rho_B \parallel \sigma_B),$$

and similarly for  $\hat{D}$ .

- **Superadditivity:**

$$D(\rho_{AB} \parallel \sigma_A \otimes \sigma_B) \geq D(\rho_A \parallel \sigma_A) + D(\rho_B \parallel \sigma_B).$$

- **Data-processing inequality:** for every quantum channel  $T$  and  $\rho, \sigma \in \mathbb{S}(\mathbb{H})$ ,

$$D(T(\rho) \parallel T(\sigma)) \leq D(\rho \parallel \sigma),$$

and similarly for  $\hat{D}$ .

**Remark 4.15** The quantum (Umegaki) relative entropy can be defined as the unique function satisfying the properties of Proposition [4.14](#).

## 4.2. Divergences

**Definition 4.16** For  $\alpha \in (0, 1) \cup (1, \infty)$ , the **Rényi divergence** between PMFs  $\{p_i\}$  and  $\{q_i\}$  is

$$D_\alpha(\{p_i\} \parallel \{q_i\}) = \frac{1}{\alpha - 1} \log \frac{\sum_i p_i^\alpha q_i^{1-\alpha}}{\sum_i p_i}.$$

Note that  $\lim_{\alpha \rightarrow 1} D_\alpha(p \parallel q) = D(p \parallel q)$  where

$$D(p \parallel q) = \sum_i p_i \log \frac{p_i}{q_i}$$

is the Kullback-Leibler divergence.

**Definition 4.17** A **quantum divergence** (with parameter  $\alpha$ ) is a function  $\mathbb{D}_\alpha(\cdot \parallel \cdot) : \mathbb{S}(\mathbb{H}) \times \mathbb{S}(\mathbb{H}) \rightarrow \mathbb{R}_{\geq 0}$  which can be expressed as  $\mathbb{D}_\alpha(\cdot \parallel \cdot) = g(Q(\cdot \parallel \cdot))$  where  $g$  is continuous and strictly monotone, and satisfies:

- **Positive semidefiniteness:**  $\mathbb{D}_\alpha(\rho \parallel \sigma) \geq 0$  with equality iff  $\rho = \sigma$ .

- **Data processing inequality:**  $\mathbb{D}_\alpha(T(\rho) \parallel T(\sigma)) \leq \mathbb{D}_\alpha(\rho \parallel \sigma)$  for every quantum channel  $T$ .
- **Additivity:**
- **Joint convexity:** if  $\alpha > 1$ , then for all  $\{p_i\}$  such that each  $p_i \geq 0$  and  $\sum_i p_i = 1$ ,

$$Q\left(\sum_i p_i \rho_i \parallel \sum_i p_i \sigma_i\right) \leq \sum_i p_i Q(\rho_i \parallel \sigma_i),$$

- **Joint concavity:** if  $\alpha \in (0, 1)$ , then for all  $\{p_i\}$  such that each  $p_i \geq 0$  and  $\sum_i p_i = 1$ ,

$$Q\left(\sum_i p_i \rho_i \parallel \sum_i p_i \sigma_i\right) \geq \sum_i p_i Q(\rho_i \parallel \sigma_i),$$

- **Dominance:** for all  $X, Y, Y' \in \mathbb{B}(\mathbb{H})$  positive with  $Y \leq Y'$ , we have  $\mathbb{D}_\alpha(X \parallel Y) \geq \mathbb{D}_\alpha(X \parallel Y')$ .

Note that unlike in the classical case, there are multiple families of functions which satisfy these axioms.

**Definition 4.18** Given orthogonal projections  $P_1, \dots, P_n$  (i.e. each  $P_i = P_i^*$  and  $\sum_i P_i = \mathbb{I}$ ), we define the **pinching map**  $\mathcal{P} : \mathbb{B}(\mathbb{H}) \rightarrow \mathbb{B}(\mathbb{H})$  by

$$\mathcal{P}(L) = \sum_{j=1}^n P_j L P_j = \sum_{k=1}^n U_k L U_k^*,$$

where  $U_k = \sum_{j=1}^n e^{2\pi i j k / n} P_j$ . It is easy to see that  $\mathcal{P}$  is a CPTP map.

**Remark 4.19** For  $H = \sum_j \lambda_j |e_j\rangle\langle e_j|$  Hermitian, we can set  $P_\lambda = \sum_{j: \lambda_j = \lambda} |e_j\rangle\langle e_j|$  so that  $H = \sum_\lambda \lambda P_\lambda$ . We can then define the pinching map  $\mathcal{P}_H : L \rightarrow \sum_\lambda P_\lambda L P_\lambda$  of  $H$ . This has the following properties:

- $P_H(L) \geq \frac{1}{|\text{spec}(H)|} L$ : note that  $|\text{spec}(H^{\otimes n})| = O(\text{poly}(n))$ .
- $[P_H(L), H] = 0$ .
- $\text{tr}(P_H(L)H) = \text{tr}(LH)$ .
- We can express  $P_H$  as an integral:  $P_H(L) = \int H^{it} L H^{-it} \mu(dt)$ .

**Definition 4.20** For  $\rho, \sigma \in \mathbb{S}(\mathbb{H})$ , let  $\Delta = \sigma^{-1/2} \rho \sigma^{-1/2} = \sum_{k=1}^m \lambda_k \Pi_k$  be the spectral decomposition. Define  $q_k = \text{tr}(\sigma \Pi_k)$  and  $p_k = \lambda_k q_k$  for each  $k \in [m]$  (note  $p$  and  $q$  can be interpreted as classical probability distributions). The **preparation map** of  $\rho$  and  $\sigma$  is

$$\Lambda(L) = \sum_{k=1}^m \langle k | L | k \rangle \frac{1}{q(k)} \sigma^{1/2} \Pi_k \sigma^{1/2}.$$

It is easy to see that  $\Lambda(p) = \rho$  and  $\Lambda(q) = \sigma$  (where we interpret  $p$  and  $q$  as the matrices  $\text{diag}(p) = \sum_{k=1}^m p_k |k\rangle\langle k|$  and  $\text{diag}(q) = \sum_{k=1}^m q_k |k\rangle\langle k|$ ). Note that  $\Lambda$  is a CPTP map.

**Definition 4.21** For  $\rho, \sigma \in \mathbb{S}(\mathbb{H})$  and  $\alpha \in (0, 1) \cup (1, \infty)$ , the **minimal/sandwiched Rényi divergence** is

$$\begin{aligned}\tilde{D}_\alpha(\rho \parallel \sigma) &:= \frac{1}{\alpha-1} \log \operatorname{tr} \left( (\sigma^{(1-\alpha)/2\alpha} \rho \sigma^{(1-\alpha)/2\alpha})^\alpha \right) = \lim_{n \rightarrow \infty} \frac{1}{n} \mathbb{D}_\alpha(\mathcal{P}_{\sigma^{\otimes n}}(\rho^{\otimes n}) \parallel \sigma^{\otimes n}) \\ &= \lim_{n \rightarrow \infty} \frac{1}{n} \mathbb{D}_\alpha(\mathcal{P}_{\sigma^{\otimes n}}(\rho^{\otimes n}) \parallel \mathcal{P}_{\sigma^{\otimes n}}(\sigma^{\otimes n})),\end{aligned}$$

where  $\mathcal{P}_{\sigma^{\otimes n}}$  is the pinching map of  $\sigma^{\otimes n}$  and  $\mathbb{D}_\alpha$  is *any* quantum divergence. By the data processing inequality, this is at most  $\lim_{n \rightarrow \infty} \frac{1}{n} \mathbb{D}_\alpha(\rho^{\otimes n} \parallel \sigma^{\otimes n}) = \mathbb{D}_\alpha(\rho \parallel \sigma)$ .

**Definition 4.22** For  $\alpha \in (1, 2)$ , the **geometric mean** of  $\rho, \sigma \in \mathbb{S}(\mathbb{H})$  is

$$\sigma \#_\alpha \rho = \sigma^{1/2} (\sigma^{-1/2} \rho \sigma^{-1/2})^\alpha \sigma^{1/2}.$$

**Definition 4.23** For  $\rho, \sigma \in \mathbb{S}(\mathbb{H})$  and  $\alpha \in (1, 2)$ , the **maximal/geometric Rényi divergence** of  $\rho$  and  $\sigma$  is

$$\hat{D}_\alpha(\rho \parallel \sigma) = \frac{1}{\alpha-1} \log \operatorname{tr} (\sigma (\sigma^{-1/2} \rho \sigma^{-1/2})^\alpha) = \frac{1}{\alpha-1} \log \operatorname{tr} (\sigma \#_\alpha \rho) = \mathbb{D}_\alpha(p \parallel q),$$

where  $p$  and  $q$  are as in Definition 4.20 and  $\mathbb{D}_\alpha$  is *any* quantum divergence. (Again, we interpret  $p$  and  $q$  as diagonal matrices.) Note that this is at least  $\mathbb{D}_\alpha(\rho \parallel \sigma) = \mathbb{D}_\alpha(\Lambda(p) \parallel \Lambda(q))$  by the (classical) data processing inequality, where  $\Lambda$  is the preparation map of  $\rho$  and  $\sigma$ .

**Proposition 4.24**

- We have  $\hat{D}_\alpha(\rho \parallel \sigma) \geq \tilde{D}_\alpha(\rho \parallel \sigma)$  with equality iff  $[\rho, \sigma] = 0$ .
- $\lim_{\alpha \rightarrow 1} \hat{D}_\alpha(\rho \parallel \sigma) = \hat{D}(\rho \parallel \sigma)$ .
- $\lim_{\alpha \rightarrow 1} \tilde{D}_\alpha(\rho \parallel \sigma) = D(\rho \parallel \sigma)$ .

**Definition 4.25** For  $\alpha \in (0, 1) \cup (1, \infty)$  and  $\rho, \sigma \in \mathbb{S}(\mathbb{H})$ , the **Petz Rényi divergence** is

$$\overline{D}_\alpha(\rho \parallel \sigma) = \frac{1}{\alpha-1} \log \operatorname{tr} (\rho^\alpha \sigma^{1-\alpha}).$$

We have  $\lim_{\alpha \rightarrow 1} \overline{D}_\alpha(\rho \parallel \sigma) = D(\rho \parallel \sigma)$ .

**Definition 4.26** The **max relative entropy** is

$$D_{\max}(\rho \parallel \sigma) = \inf \{ \lambda > 0 : \rho \leq 2^\lambda \sigma \}.$$

We have  $D_{\max}(\rho \parallel \sigma) = \lim_{\alpha \rightarrow \infty} \overline{D}_\alpha(\rho \parallel \sigma)$ .

**Proposition 4.27** For all  $\alpha \in (1, 2)$ ,

$$D(\rho \parallel \sigma) \leq \tilde{D}_\alpha(\rho \parallel \sigma) \leq \overline{D}_\alpha(\rho \parallel \sigma) \leq \hat{D}_\alpha(\rho \parallel \sigma) \leq D_{\max}(\rho \parallel \sigma).$$

### 4.3. Applications

Recall the setting of binary hypothesis testing from the previous chapter. Given  $n$  copies of the states  $\rho, \sigma \in \mathbb{S}(\mathbb{H})$ , the null hypothesis is  $\rho^{\otimes n}$  and the alternative hypothesis is  $\sigma^{\otimes n}$ . We want to discriminate between both by considering POVMs  $M_n = \{P_n, \mathbb{I} - P_n\}$ , with  $P_n$  an orthogonal projection.

Type I (first kind) error occurs if we wrongly conclude that alternative hypothesis is correct, with probability  $\alpha_n(P_n; \rho) := \text{tr}(\rho^{\otimes n}(\mathbb{I} - P_n))$ . Type II (second kind) error occurs if we wrongly conclude that the null hypothesis is correct, with probability  $\beta_n(P_n; \sigma) := \text{tr}(\sigma^{\otimes n} P_n)$ .

By [Quantum Neyman-Pearson](#), we have

$$\min_{M_n \text{ POVM}} \frac{1}{2}(\alpha_n(P_n; \rho) + \beta_n(P_n; \sigma)) = \frac{1}{2}(1 - \|p\rho^{\otimes n} - (1-p)\sigma^{\otimes n}\|_1),$$

and taking the limit as  $n \rightarrow \infty$  gives

$$\begin{aligned} \lim_{n \rightarrow \infty} -\frac{1}{n} \log \min_{M_n \text{ POVM}} \frac{1}{2}(\alpha_n(P_n; \rho) + \beta_n(P_n; \sigma)) &= \max_{s \in [0,1]} -\text{tr}(\rho^s \sigma^{1-s}) \\ &= -\min_{s \in [0,1]} \log \overline{Q}_s(\rho \parallel \sigma) \\ &= \max_{s \in [0,1]} (1-s) \overline{D}_s(\rho \parallel \sigma), \end{aligned}$$

where  $\overline{D}_s(\rho \parallel \sigma)$  is the Petz Rényi divergence, and  $\overline{Q}_s = \text{tr}(\rho^s \sigma^{1-s})$  is as in Definition [4.17](#).

So the interpretation of the Petz Rényi divergence is that it provides optimal exponential rate for the combined errors in binary hypothesis testing.

Similarly, we can consider the setting of asymmetric hypothesis testing. By the [Quantum Stein's Lemma](#),

$$\lim_{n \rightarrow \infty} -\frac{1}{n} \log \beta_n(P_n; \sigma) = D(\rho \parallel \sigma),$$

so the relative entropy can be interpreted as being the optimal exponential rate for the type II error in binary hypothesis, subject to the type I error being bounded by a certain constant.

For probability distributions  $P$  and  $Q$  and  $\alpha \in (1, \infty)$ , we have  $D_\alpha(P \parallel Q) = \sum_x P(x) \left( \frac{P(x)}{Q(x)} \right)^{\alpha-1}$ . We have the chain rule for classical Rényi divergence:

$$D_\alpha(P_{XY} \parallel Q_{X,Y}) \leq D_\alpha(P_X \parallel Q_X) + \max_x D(P_{Y \mid X=x} \parallel Q_{Y \mid X=x}).$$

**Definition 4.28** Let  $\mathbb{D}_\alpha$  be a quantum Rényi divergence. We can extend this to a **Rényi divergence of quantum channels** by defining, for quantum channels  $T_1, T_2$ ,

$$\mathbb{D}_\alpha(T_1 \parallel T_2) := \sup_{\rho \in \mathbb{S}(\mathbb{H})} \mathbb{D}_\alpha(T_1(\rho) \parallel T_2(\rho)).$$

**Lemma 4.29** For  $\rho, \sigma \in \mathbb{S}(\mathbb{H})$ ,  $\alpha \in (0, 1) \cup (1, 2]$ , we have

$$\hat{D}_\alpha(\rho \parallel \sigma) = \inf_{P, Q, \Lambda} D_\alpha(P \parallel Q)$$

where  $\Lambda(P) = \rho$ ,  $\Lambda(Q) = \sigma$ ,  $\Lambda$  is a quantum channel.

The infimum is attained by the following: let  $\sigma^{-1/2}\rho\sigma^{-1/2} = \sum_x \lambda_x \Pi_x$ , define  $\Lambda(L) = \sum_x \frac{\langle x|L|x\rangle}{Q(x)} \sigma^{1/2} \Pi_x \sigma^{1/2}$ , with  $Q(x) = \text{tr}(\sigma \Pi_x)$ ,  $P(x) = \lambda_x Q(x)$ .

**Theorem 4.30** (Chain Rule for Quantum Channels) Let  $\rho, \sigma \in \mathbb{S}(\mathbb{H})$ ,  $T_1, T_2$  be quantum channels and  $\alpha \in (0, 1) \cup (1, \infty)$ , then

$$\mathbb{D}_\alpha(T_1(\rho) \parallel T_2(\sigma)) \leq \hat{D}_\alpha(\rho \parallel \sigma) + \mathbb{D}_\alpha(T_1 \parallel T_2).$$

for any quantum Rényi divergence  $\mathbb{D}_\alpha$ . In particular,  $\hat{D}_\alpha(T_1(\rho) \parallel T_2(\sigma)) \leq \hat{D}_\alpha(\rho \parallel \sigma) + \hat{D}_\alpha(T_1 \parallel T_2)$ .

*Proof (Hints).*

- Let  $P, Q, \Lambda$  be as in Lemma 4.29, show that  $T_1(\rho) = \sum_x P(x) T_1(\Lambda(|x\rangle\langle x|))$ , similarly for  $T_2(\sigma)$ .
- Explain why

$$\frac{1}{\alpha - 1} \log \sum_x P(x)^\alpha Q(x)^{1-\alpha} \cdot 2^{\mathbb{D}_\alpha(T_1(\Lambda(|x\rangle\langle x|)) \parallel T_2(\Lambda(|x\rangle\langle x|)))},$$

split the sum by the taking a maximum over the second terms in the sum.

□

*Proof.* By Lemma 4.29, there are  $P$  and  $Q$  such that  $\Lambda(P) = \rho$  and  $\Lambda(Q) = \sigma$ . So we have, by linearity of quantum channels,

$$\begin{aligned} T_1(\rho) &= T_1(\Lambda(P)) = T_1\left(\Lambda\left(\sum_x P(x)|x\rangle\langle x|\right)\right) = \sum_x P(x) T_1(\Lambda(|x\rangle\langle x|)) \\ T_2(\sigma) &= T_2(\Lambda(Q)) = T_2\left(\Lambda\left(\sum_x Q(x)|x\rangle\langle x|\right)\right) = \sum_x Q(x) T_2(\Lambda(|x\rangle\langle x|)) \end{aligned}$$

Then (since we can treat these classically as they are diagonal)

$$\begin{aligned} \mathbb{D}_\alpha(T_1(\rho) \parallel T_2(\sigma)) &= \mathbb{D}_\alpha\left(\sum_x P(x) T_1(\Lambda(|x\rangle\langle x|)) \parallel \sum_x Q(x) T_2(\Lambda(|x\rangle\langle x|))\right) \\ &\leq \frac{1}{\alpha - 1} \log \sum_x P(x)^\alpha Q(x)^{1-\alpha} \cdot 2^{\mathbb{D}_\alpha(T_1(\Lambda(|x\rangle\langle x|)) \parallel T_2(\Lambda(|x\rangle\langle x|)))} \\ &\leq D_\alpha(P \parallel Q) + \max_x \mathbb{D}_\alpha(T_1(\Lambda(|x\rangle\langle x|)) \parallel T_2(\Lambda(|x\rangle\langle x|))) \\ &\leq \hat{D}_\alpha(\Lambda(\rho) \parallel \Lambda(\sigma)) + \mathbb{D}_\alpha(T_1 \parallel T_2) \\ &\leq \hat{D}_\alpha(\rho \parallel \sigma) + \mathbb{D}_\alpha(T_1 \parallel T_2), \end{aligned}$$

where the final inequality is by data-processing. □

**Definition 4.31** The **regularised Rényi divergence** between quantum channels  $T_1$  and  $T_2$  is

$$\mathbb{D}_\alpha^{\text{reg}}(T_1 \parallel T_2) := \lim_{n \rightarrow \infty} \frac{1}{n} \mathbb{D}_\alpha(T_1^{\otimes n} \parallel T_2^{\otimes n})$$

This equals  $\mathbb{D}_\alpha(T_1 \parallel T_2)$  if  $\mathbb{D}_\alpha$  is the geometric Rényi divergence, but this generally does not hold for other quantum divergences.

**Theorem 4.32** (Schumacher) Let  $\{|\psi(x)\rangle, p(x)\}_x$  be an ensemble of states  $|\psi(x)\rangle$  with probabilities  $p(x)$ . Let  $\rho = \sum_x p(x) |\psi(x)\rangle \langle \psi(x)|$ . Then the optimal rate of compression is given by the von Neumann entropy of  $\rho$ .
