0.1. Prerequisites

- Definition: $I \subset R$ is prime ideal if $\forall a, b \in R, ab \in I \Longrightarrow a \in I \lor b \in I$.
- **Definition**: ideal I is **maximal** if $I \neq R$ and there is no ideal $J \subset R$ such that $I \subset J$.
- Example:
 - $p \in \mathbb{Z}$ is prime iff $\langle p \rangle = p\mathbb{Z}$ is prime ideal.
 - $\langle 0 \rangle$ is prime ideal iff R is integral domain.
- **Lemma**: if *I* is maximal ideal, then it is prime.
- **Proposition**: for commutative ring R, ideal I:
 - $I \subset R$ is prime ideal iff R/I is an integral domain.
 - I is maximal iff R/I is field.
- **Proposition**: let R be PID and $a \in R$ irreducible. Then $\langle a \rangle = \langle a \rangle_R$ is maximal.
- **Theorem**: let F be field, $f(x) \in F[x]$ irreducible. Then $F[x]/\langle f(x) \rangle$ is a field and a vector space over F with basis $B = \{1, \overline{x}, ..., \overline{x}^{n-1}\}$ where $n = \deg(f)$. That is, every element in $F[x]/\langle f(x) \rangle$ can be uniquely written as linear combination

$$\overline{a_0 + a_1 x + \dots + a_{n-1} x^{n-1}}, \quad a_i \in F$$

1. Divisibility in rings

1.1. Every ED is a PID

- Definition: let R integral domain. $\varphi: R \{0\} \to \mathbb{N}_0$ is Euclidean function (norm) on R if:
 - $\forall x, y \in R \{0\}, \varphi(x) \le \varphi(xy)$.
 - $\forall x \in R, y \in R \{0\}, \exists q, r \in R : x = qy + r \text{ with either } r = 0 \text{ or } \varphi(r) < \varphi(y).$

R is **Euclidean domain (ED)** if Euclidean function is defined on it.

- Example:
 - \mathbb{Z} is ED with $\varphi(n) = |n|$.
 - F[x] is ED for field F with $\varphi(f) = \deg(f)$.
- Lemma: $\mathbb{Z}[-\sqrt{2}]$ is ED with Euclidean function

$$\varphi(a+b\sqrt{-2})=N(a+b\sqrt{-2})\eqqcolon a^2+2b^2$$

• **Proposition**: every ED is a PID.

1.2. Every PID is a UFD

- Definition: Integral domain R is unique factorisation domain (UFD) if every non-zero non-unit in R can be written uniquely (up to order of factors and multiplication by units) as product of irreducible elements in R.
- Example: let $R = \{f(x) \in \mathbb{Q}[x] : f(0) \in \mathbb{Z}\}$. Its units are ± 1 . Any factorisation of $x \in R$ must be of the form f(x)g(x) where $\deg f = 1, \deg g = 0$, so x = (ax + b)c, $a \in \mathbb{Q}$, $b, c \in \mathbb{Z}$. We have bc = 0 and ac = 1 hence $x = \frac{x}{c} \cdot c$. So x irreducible if $c \neq \pm 1$. Also, any factorisation of $\frac{x}{c}$ in R is of the form $\frac{x}{c} = \frac{x}{cd} \cdot d$, $d \in \mathbb{Z}$, $d \neq 0$. Again, neither factor is a unit when $d \neq \pm 1$. So $x = \frac{x}{c} \cdot c = \frac{x}{cd} \cdot c \cdot c = \cdots$ can never be decomposed into irreducibles (the first factor is never irreducible).

- Lemma: let R be PID. Then every irreducible element is prime in R.
- **Theorem**: every PID is a UFD.
- **Example**: $\mathbb{Z}\left[\sqrt{-2}\right]$ so by the above theorem it is a UFD. Let $x, y \in \mathbb{Z}$ such that $y^2 + 2 = x^3$.
 - y must be odd, since if $y = 2a, a \in \mathbb{Z}$ then $x = 2b, b \in \mathbb{Z}$ but then $2a^2 + 1 = 4b^3$.
 - $y \pm \sqrt{-2}$ are relatively prime: if $a + b\sqrt{-2}$ divides both, then it divides their difference $2\sqrt{-2}$, so norm $a^2 + 2b^2 \mid N(2\sqrt{-2}) = 8$. Only possible case is $a = \pm 1, b = 0$ so $a + b\sqrt{-2}$ is unit. Other cases $a = 0, b = \pm 1, a = \pm 2, b = 0$ and $a = 0, b = \pm 2$ are impossible since y not even.
 - If $a + b\sqrt{-2}$ is unit, $\exists x, y \in \mathbb{Z} : (a + b\sqrt{-2})(x + y\sqrt{-2}) = 1$. If $b \neq 0$ then $(-a^2 2b^2)y = 1 \Longrightarrow b = 0$: contradiction. If b = 0, $a = \pm 1$.

2. Finite field extensions

- **Definition**: let F, L fields. If $F \subseteq L$ and F and L share the same operations then F is a **subfield** of L and L is **field extension** of F (denoted L/F). L is vector space over F:
 - $0 \in L$ (zero vector).
 - $u, v \in L \Longrightarrow u + v \in L$ (additivity).
 - $a \in F, u \in L \Longrightarrow au \in L$ (scalar multiplication).
- **Definition**: let L/F field extension. **Degree** of L over F is dimension of L as vector space over F:

$$[L:F] \coloneqq \dim_F(L)$$

If [L:F] finite, L/F is finite field extension.

- Example: $\mathbb{Q}(\sqrt{-2}) = \{a + b\sqrt{-2} : a, b \in \mathbb{Q}\}$ is isomorphic as a vector space to \mathbb{Q}^2 so is 2-dimensional vector space over \mathbb{Q} . Isomorphism is $a + b\sqrt{-2} \longleftrightarrow (a, b)$. Standard basis $\{e_1, e_2\}$ in \mathbb{Q}^2 corresponds to the basis $\{1, \sqrt{-2}\}$ in $\mathbb{Q}(\sqrt{-2})$. $|\mathbb{Q}(\sqrt{-2}):\mathbb{Q}| = 2$.
- **Example**: $[\mathbb{C} : \mathbb{R}] = 2$ (a basis is $\{1, i\}$). $[\mathbb{R} : \mathbb{Q}]$ is not finite, due to the existence of transcendental numbers (if α transcendental, then $\{1, \alpha, \alpha^2, ...\}$ is linearly independent).
- **Definition**: let L/F field extension. $\alpha \in L$ is **algebraic** over F if

$$\exists f(x) \in F[x] : f(\alpha) = 0$$

If all elements in L are algebraic, then L/F is algebraic field extension.

- **Example**: $i \in \mathbb{C}$ is algebraic over \mathbb{R} since i is root of $x^2 + 1$. \mathbb{C}/\mathbb{R} is algebraic since z = a + bi is root of $(x z)(x \overline{z}) = x^2 2ax + a^2 + b^2$.
- **Proposition**: if L/F is finite field extension then it is algebraic.
- **Definition**: let L/F field extension, $\alpha \in L$ algebraic over F. **Minimal polynomial** $p_{\alpha}(x) = p_{\alpha,F}(x)$ of α over F is the monic polynomial f of smallest degree such that $f(\alpha) = 0$. **Degree** of α over F is $\deg(p_{\alpha})$.
- **Proposition**: $p_{\alpha}(x)$ is unique and irreducible. Also, if $f(x) \in F[x]$ is monic, irreducible and $f(\alpha) = 0$, then $f = p_{\alpha}$.

- Example:
 - $p_{i,\mathbb{R}}(x) = p_{i,\mathbb{Q}}(x) = x^2 + 1, p_{i,\mathbb{Q}(i)}(x) = x i.$
 - Let $\alpha = \sqrt[7]{5}$. $f(x) = x^7 5$ is minimal polynomial of α over \mathbb{Q} , as it is irreducible by Eisenstein's criterion with p = 5 and the above proposition.
 - Let $\alpha = e^{2\pi i/p}$, p prime. α is algebraic as root of $x^p 1$ which isn't irreducible as $x^p 1 = (x 1)\Phi(x)$ where $\Phi(x) = (x^{p-1} + \cdots + 1)$. $\Phi(\alpha) = 0$ since $\alpha \neq 1$, $\Phi(x)$ is monic and $\Phi(x + 1) = ((x + 1)^p 1)/x$ irreducible by Eisenstein's criterion with p = p, hence $\Phi(x)$ irreducible. So $p_{\alpha}(x) = \Phi(x)$.

2.1. Fields generated by elements

• Definition: let L/F field extension, $\alpha \in L$. The field generated by α over F is the smallest subfield of L containing F and α :

$$F(\alpha) \coloneqq \bigcap_{\substack{K \text{ field,} \\ F \subseteq K \subseteq L, \\ \alpha \in K}} K$$

Generally, $F(\alpha_1, ..., \alpha_n)$ is smallest field extension of F containing $\alpha_1, ..., \alpha_n$.

- We have $F(\alpha_1, ..., \alpha_n) = F(\alpha_1) \cdot \cdot \cdot \cdot (\alpha_n)$ (show $F(\alpha, \beta) \subseteq F(\alpha)(\beta)$ and $F(\alpha)(\beta) \subseteq F(\alpha, \beta)$ by minimality and use induction).
- Definition: $F[\alpha]=\{\sum_{i=0}^n a_i\alpha^i: a_i\in F, n\in\mathbb{N}\}=\{f(\alpha): f(x)\in F[x]\}.$
- Lemma: let L/F field extension, $\alpha \in L$ algebraic over F. Then $F[\alpha]$ is field, hence $F(\alpha) = F[\alpha]$.
- Lemma: let α algebraic over F. Then $[F(\alpha):F]=\deg(p_{\alpha})$.
- **Definition**: let K/F and L/K field extensions, then $F \subseteq K \subseteq L$ is **tower of** fields.
- Tower theorem: let $F \subseteq K \subseteq L$ tower of fields. Then

$$[L:F] = [L:K] \cdot [K:F]$$

- Example: let $L = \mathbb{Q}(\sqrt{2}, \sqrt{3})$. Show $[L : \mathbb{Q}] = 4$.
 - Let $K = \mathbb{Q}(\sqrt{2})$. Let $\sqrt{3} = a + b\sqrt{2}$, $a, b \in \mathbb{Q}$ so $3 = a^2 + 2b^2 + 2ab\sqrt{2}$. So $0 \in \{a, b\}$, otherwise $\sqrt{2} \in \mathbb{Q}$. But if a = 0, then $\sqrt{6} = 2b \in \mathbb{Q}$, if b = 0 then $\sqrt{3} = a \in \mathbb{Q}$: contradiction. So $x^2 3$ has no roots in K so is irreducible over K so $p_{\sqrt{3},K}(x) = x^2 3$.
 - So [L:K]=2 so by the tower theorem, $[L:\mathbb{Q}]=[L:K]\cdot [K:\mathbb{Q}]=4.$

2.2. Norm and trace

• Let L/F finite field extension, n = [L:F]. For any $\alpha \in L$, there is F-linear map

$$\hat{\alpha}: L \longrightarrow L, \quad x \mapsto \alpha x$$

• With basis $\{\alpha_1, ..., \alpha_n\}$ of L over F, let $T_{\alpha} = T_{\alpha, L/F} \in M_n(F)$ be the corresponding matrix of the linear map α with respect to the basis $\{\alpha_i\}$:

$$\begin{split} \hat{\alpha}(\alpha_1) &= \alpha \alpha_1 = a_{1,1} \alpha_1 + \dots + a_{1,n} \alpha_n, \\ &\vdots \\ \hat{\alpha}(\alpha_n) &= \alpha \alpha_n = a_{n,1} \alpha_1 + \dots + \alpha_{n,n} \alpha_n \end{split}$$

with $a_{i,j} \in F$, $T_{\alpha} = (a_{i,j})$, so α is eigenvalue of T_{α} :

$$\alpha \begin{bmatrix} \alpha_1 \\ \vdots \\ \alpha_n \end{bmatrix} = T_\alpha \begin{bmatrix} \alpha_1 \\ \vdots \\ \alpha_n \end{bmatrix}$$

• **Definition**: **norm** of α is

$$N_{L/F}(\alpha)\coloneqq \det(T_\alpha)$$

• **Definition**: **trace** of α is

$$\operatorname{tr}_{L/F}(\alpha) := \operatorname{tr}(T_{\alpha})$$

- Remark: norm and trace are independent of choice of basis so are well-defined (uniquely determined by α).
- Example: let $L = \mathbb{Q}(\sqrt{m}), m \in \mathbb{Z}$ non-square, let $\alpha = a + b\sqrt{m} \in L$. Fix basis $\{1,\sqrt{m}\}$. Now

$$\begin{split} \hat{\alpha}(1) &= \alpha \cdot 1 = a + b\sqrt{m}, \\ \hat{\alpha}\left(\sqrt{m}\right) &= \alpha\sqrt{m} = bm + a\sqrt{m}, \\ T_{\alpha} &= \begin{bmatrix} a & b \\ bm & a \end{bmatrix} \end{split}$$

So $N_{L/F}(\alpha) = a^2 - b^2 m$, $\operatorname{tr}_{L/F}(\alpha) = 2a$.

• Lemma: the map $L \to M_n(F)$ given by $\alpha \mapsto T_\alpha$ is injective ring homomorphism. So if $f(x) \in F[x]$,

$$T_{f(\alpha)} = f(T_{\alpha})$$

 $(f(T_{\alpha}))$ is a polynomial in T_{α} , not f applied to each entry).

- **Proposition**: let L/F finite field extension. $\forall \alpha, \beta \in L$,
 - $N_{L/F}(\alpha) = 0 \iff \alpha = 0.$

 - $\begin{array}{ll} \bullet & N_{L/F}(\alpha\beta) = N_{L/F}(\alpha)N_{L/F}(\beta). \\ \bullet & \forall a \in F, N_{L/F}(a) = a^{[L:F]} \text{ and } \operatorname{tr}_{L/F}(a) = [L:F]\alpha. \end{array}$
 - $\forall a, b \in F$, $\operatorname{tr}_{L/F}(a\alpha + b\beta) = a \operatorname{tr}_{L/F}(\alpha) + b \operatorname{tr}_{L/F}(\beta)$ (so $\operatorname{tr}_{L/F}$ is F-linear map).

2.3. Characteristic polynomials

- Let $A \in M_n(F)$, then characteristic polynomial is $\chi_A(x) = \det(xI A) \in F[x]$ and is monic, $\deg(\chi_A) = n$. If $\chi_A(x) = x^n + \sum_{i=0}^{n-1} c_i x^i$ then $\det(A) = (-1)^n \det(0 - A) = (-1)^n \chi_A(0) = (-1)^n c_0$ and $\operatorname{tr}(A) = -c_{n-1}$, since if $\alpha_1, ..., \alpha_n$ are eigenvalues of A (in some field extension of F), then $tr(A) = \alpha_1 + \dots + \alpha_n,$ $\chi_A(x) = (x - \alpha_1) \cdot \cdot \cdot (x - \alpha_n) = x^n - (\alpha_1 + \cdot \cdot \cdot \alpha_n) x^{n-1} + \cdot \cdot \cdot$
- For finite extension L/F, n = [L : F], $\alpha \in L$, characteristic polynomial $\chi_{\alpha}(x) = \chi_{\alpha,L/F}(x)$ is characteristic polynomial of T_{α} . So $N_{L/F}(\alpha) = (-1)^n c_0$, $\mathrm{tr}_{L/F}(\alpha)=-c_{n-1}.$ By the Cayley-Hamilton theorem, $\chi_{\alpha}(T_{\alpha})=0$ so $T_{\chi_{\alpha}(\alpha)} = \chi_{\alpha}(T_{\alpha}) = 0$, where $\chi_{\alpha}(x) = x^n + c_{n-1}x^{n-1} + \cdots + c_0$. Since $\alpha \to T_{\alpha}$ is injective, $\chi_{\alpha}(\alpha) = 0$.

- Lemma: let L/F finite extension, $\alpha \in L$ with $L = F(\alpha)$. Then $\chi_{\alpha}(x) = p_{\alpha}(x)$.
- Proposition: let $F \subseteq F(\alpha) \subseteq L$, let $m = [L : F(\alpha)]$. Then $\chi_{\alpha}(x) = p_{\alpha}(x)^{m}$.
- Corollary: let L/F, $\alpha \in L$ as above, $p_{\alpha}(x) = x^d + a_{d-1}x^{d-1} + \cdots + a_0$, $a_i \in F$. Then

$$N_{L/F}(\alpha) = (-1)^{md} a_0^m, \quad \operatorname{tr}_{L/F}(\alpha) = -m a_{d-1}$$

3. Algebraic number fields and algebraic integers

3.1. Algebraic numbers

- **Definition**: $\alpha \in \mathbb{C}$ is algebraic number if algebraic over \mathbb{Q} .
- Definition: K is (algebraic) number field if $\mathbb{Q} \subseteq K \subseteq \mathbb{C}$ and $[K : \mathbb{Q}] < \infty$.
- Every element of an algebraic number field is an algebraic number.
- Example: let $\theta = \sqrt{2} + \sqrt{3}$, then $\mathbb{Q}(\theta) \subseteq \mathbb{Q}(\sqrt{2}, \sqrt{3})$ but also $\theta^3 = 11\sqrt{2} + 9\sqrt{3}$ so

$$\sqrt{2} = \frac{\theta^3 - 9\theta}{2}, \quad \sqrt{3} = \frac{-\theta^3 + 11\theta}{2}$$

so $\mathbb{Q}(\sqrt{2}, \sqrt{3}) \subseteq \mathbb{Q}(\theta)$ hence $\mathbb{Q}(\sqrt{2}, \sqrt{3}) = \mathbb{Q}(\theta)$.

- Simple extension theorem: every number field K has form $K = \mathbb{Q}(\theta)$ for some $\theta \in K$.
- Set of all algebraic numbers (union of all number fields) is denoted $\overline{\mathbb{Q}}$ and is a field, since if $\alpha \neq 0$ algebraic over \mathbb{Q} , $[\mathbb{Q}(\alpha):\mathbb{Q}] = \deg(p_{\alpha}) < \infty$ so $\mathbb{Q}(\alpha)/\mathbb{Q}$ algebraic, so $-\alpha, \alpha^{-1} \in \mathbb{Q}(\alpha)$ algebraic, so $\alpha^{-1}, -\alpha \in \overline{\mathbb{Q}}$, and if $\alpha, \beta \in \overline{\mathbb{Q}}$ then $\mathbb{Q}(\alpha, \beta) = \mathbb{Q}(\alpha)(\beta)$ is finite extension of \mathbb{Q} by tower theorem so $\alpha + \beta$, $\alpha\beta \in \mathbb{Q}(\alpha, \beta)$ so are algebraic.
- $[\overline{\mathbb{Q}}:\mathbb{Q}] = \infty$ since if $[\overline{\mathbb{Q}}:\mathbb{Q}] = d \in \mathbb{N}$ then every algebraic number would have degree $\leq d$, but $\sqrt[d+1]{2}$ has degree d+1 since it is a root of $x^{d+1}-2$ which is irreducible by Eisenstein's criterion with p=2.
- **Definition**: let $\alpha \in \overline{\mathbb{Q}}$. Conjugates of α are roots of $p_{\alpha}(x)$ in \mathbb{C} .
- Example:
 - Conjugate of $a + bi \in \mathbb{Q}(i)$ is a bi.
 - Conjugate of $a + b\sqrt{2} \in \mathbb{Q}(\sqrt{2})$ is $a b\sqrt{2}$.
 - Conjugates of θ do not always lie in $\mathbb{Q}(\theta)$, e.g. for $\theta = \sqrt[3]{2}$, $p_{\theta}(x) = x^3 2$ has two non-real roots not in $\mathbb{Q}(\theta) \subset \mathbb{R}$.
- Notation: when base field is \mathbb{Q} , N_K and tr_K denote $N_{K/\mathbb{Q}}$ and $\operatorname{tr}_{K/\mathbb{Q}}$.
- Lemma: let K/\mathbb{Q} number field, $\alpha \in K, \alpha_1, ..., \alpha_n$ conjugates of α . Then

$$N_K(\alpha) = (\alpha_1 \cdot \cdot \cdot \alpha_n)^{[K:\mathbb{Q}(\alpha)]}, \quad \operatorname{tr}_K(\alpha) = (\alpha_1 + \cdot \cdot \cdot + \alpha_n)[K:\mathbb{Q}(\alpha)]$$

3.2. Algebraic integers

• **Definition**: $\alpha \in \overline{\mathbb{Q}}$ is **algebraic integer** if it is root of a monic polynomial in $\mathbb{Z}[x]$. The set of algebraic integers is denoted $\overline{\mathbb{Z}}$. If K/\mathbb{Q} is number field, set of algebraic integers in K is denoted \mathcal{O}_K , $\alpha \in \mathcal{O}_K$ is called **integer in** K.

- Example: $i, (1+\sqrt{3})/2 \in \mathbb{Z}$ since they are roots of x^2+1 and x^2-x+1 respectively.
- Theorem: let $\alpha \in \overline{\mathbb{Q}}$. The following are equivalent:
 - $\alpha \in \mathbb{Z}$.

 - $\begin{array}{l} \bullet \ \ p_{\alpha}(x) \in \mathbb{Z}[x]. \\ \bullet \ \ \mathbb{Z}[\alpha] = \{\sum_{i=0}^{d-1} a_i \alpha^i : a_i \in \mathbb{Z}\} \ \text{where} \ d = \deg(p_{\alpha}). \end{array}$
 - There exists non-trivial finitely generated abelian additive subgroup $G \subset \mathbb{C}$ such that

$$\alpha G \subseteq G$$
 i.e. $\forall g \in G, \alpha g \in G$

(αq is complex multiplication).

• Remark:

- For third statement, generally we have $\mathbb{Z}[\alpha] = \{f(\alpha : f(x) \in \mathbb{Z}[x])\}$ and in this case, $\mathbb{Z}[\alpha] = \{ f(\alpha) : f(x) \in \mathbb{Z}[x], \deg(f) < d \}.$
- Fourth statement means that

$$G = \{a_1 \gamma_1 + \dots + a_r \gamma_r : a_i \in \mathbb{Z}\} = \gamma_1 \mathbb{Z} + \dots + \gamma_r \mathbb{Z} = \langle \gamma_1, ..., \gamma_r \rangle_{\mathbb{Z}}$$

G is typically $\mathbb{Z}[\alpha]$. E.g. if $\alpha = \sqrt{2}$, $\mathbb{Z}[\sqrt{2}]$ is generated by $1, \sqrt{2}$ and $\sqrt{2} \cdot \mathbb{Z}[\sqrt{2}] \subseteq \mathbb{Z}[\sqrt{2}].$

- Proposition: $\overline{\mathbb{Z}}$ is a ring. Also, for every number field $K,\,\mathcal{O}_K$ is a ring.
- Lemma: let $\alpha \in \overline{\mathbb{Z}}$. For every number field K with $\alpha \in K$,

$$N_K(\alpha) \in \mathbb{Z}, \quad \operatorname{tr}_K(\alpha) \in \mathbb{Z}$$

• Lemma: let K number field. Then

$$K = \left\{ \frac{\alpha}{m} : \alpha \in \mathcal{O}_K, m \in \mathbb{Z}, m \neq 0 \right\}$$

• Lemma: let $\alpha \in \overline{\mathbb{Z}}$, K number field, $\alpha \in K$. Then

$$\alpha \in \mathcal{O}_K^{\times} \Longleftrightarrow N_K(\alpha) = \pm 1$$

3.3. Quadratic fields and their integers

- **Definition**: $d \in \mathbb{Z}$ is **squarefree** if $d \notin \{0,1\}$ and there is no prime p such that $p^2 \mid d$.
- **Definition**: $K = \mathbb{Q}(\sqrt{d})$ is a quadratic field if d is squarefree. If d > 0 then it is real quadratic. If d < 0 it is imaginary quadratic.
- Proposition: let K/\mathbb{Q} have degree 2. Then $K=\mathbb{Q}(\sqrt{d})$ for some squarefree $d \in \mathbb{Z}$.
- Lemma: let $K = \mathbb{Q}(\sqrt{d}), d \equiv 1 \pmod{4}$. Then

$$\mathbb{Z}[\frac{1+\sqrt{d}}{2}] = \left\{ \frac{r+s\sqrt{d}}{2} : r, s \in \mathbb{Z}, r \equiv s \; (\operatorname{mod} 2) \right\}$$

• **Theorem**: let $K = \mathbb{Q}(\sqrt{d})$ quadratic field, then

$$\mathcal{O}_K = \begin{cases} \mathbb{Z}[\sqrt{d}] & \text{if } d \not\equiv 1 \pmod{4} \\ \mathbb{Z}[\frac{1+\sqrt{d}}{2}] & \text{if } d \equiv 1 \pmod{4} \end{cases}$$

4. Units in quadratic rings

- Notation: in this section, let $K = \mathbb{Q}(\sqrt{d})$ be quadratic number field, $d \in \mathbb{Z} \{0\}$, |d| is not a square. Let $\mathcal{O}_d=\mathcal{O}_K$. Let $\overline{a+b\sqrt{d}}=a-b\sqrt{d}$. The map $x\to \overline{x}$ is a \mathbb{Q} automorphism from K to K.
- Definition: S is quadratic number ring of K if $S = \mathcal{O}_d$ or $S = \mathbb{Z}[\sqrt{d}]$.
- We have

$$\alpha \in S^{\times} \Longrightarrow \exists x \in S: \alpha x = 1 \Longrightarrow N_K(\alpha)N_K(x) = 1 \Longrightarrow N_K(\alpha) = \pm 1$$

and for $\alpha \in S - \mathbb{Z}$, since $[\mathbb{Q}(\alpha) : \mathbb{Q}] = 2$ and so $[K : \mathbb{Q}(\alpha)] = 1$ by the Tower Theorem,

$$N_K(\alpha) = \pm 1 \Longrightarrow \alpha \overline{\alpha} = \pm 1 \Longrightarrow \alpha \in S^{\times}$$

So $\alpha \in S^{\times} \iff N_K(\alpha) = \pm 1$.

- **Theorem**: to determine the group of units for imaginary quadratic fields:
 - For d < -1, $\mathbb{Z}[\sqrt{d}]^{\times} = \{\pm 1\}$.
 - $\mathcal{O}_{-1}^{\times} = \mathbb{Z}[i]^{\times} = \{\pm 1, \pm i\}.$
 - For $d \equiv 1 \pmod{4}$ and d < -3, $\mathbb{Z}[\frac{1+\sqrt{d}}{2}]^{\times} = \{\pm 1\}$. $\mathbb{Z}[\frac{1+\sqrt{-3}}{2}]^{\times} = \{\pm 1, \pm \omega, \pm \omega^2\}$ where $\omega = \frac{1+\sqrt{-3}}{2} = e^{\pi i/3}$.
- Main theorem: let d > 1, d non-square, S be quadratic number ring of $K = \mathbb{Q}(\sqrt{d})$ (i.e. $S = \mathcal{O}_d$ or $S = \mathbb{Z}[\sqrt{d}]$). Then
 - S has a smallest unit u > 1 (smaller than all units except 1).
 - $S^{\times} = \{ \pm u^r : r \in \mathbb{Z} \} = \langle -1, u \rangle.$
- **Definition**: the smallest unit u > 1 above is the **fundamental unit** of S (or of K, in the case $S = \mathcal{O}_d$).

4.1. Proof of the main theorem

• Remark: if $\alpha=a+b\sqrt{d}$ is unit in $\mathbb{Z}[\sqrt{d}],\ a,b>0$, then $N_K(\alpha)=\alpha\overline{\alpha}=\pm 1$, so

$$|\overline{\alpha}| = |a - b\sqrt{d}| = \frac{|N_K(\alpha)|}{|\alpha|} = \frac{1}{|\alpha|} < \frac{1}{b\sqrt{d}} < \frac{1}{b}$$

Define

$$A = \left\{\alpha = a + b\sqrt{d} : a, b \in \mathbb{N}_0, |\overline{\alpha}| < \frac{1}{b}\right\}$$

- Lemma: $|A| = \infty$.
- Lemma: if $\alpha \in A$, then $|N_K(\alpha)| < 1 + 2\sqrt{d}$.
- Lemma: $\exists \alpha=a+b\sqrt{d}, \alpha'=a'+b'\sqrt{d} \in A: \alpha>\alpha', \ |N_K(\alpha)|=|N_K(\alpha')|=:n$ and

$$\alpha \equiv \alpha' \pmod{n}, \quad b \equiv b' \pmod{n}$$

- Lemma: there exists a unit u in $\mathbb{Z}[\sqrt{d}]$ such that u > 1.
- Lemma: let $0 \neq \alpha = a + b\sqrt{d} \in \mathbb{Q}(\sqrt{d})$. Then $\alpha > \sqrt{|N_K(\alpha)|}$ iff a, b > 0.

4.2. Computing fundamental units

- Theorem: let d > 1 non-square.
 - If $S = \mathbb{Z}[\sqrt{d}]$ and $a + b\sqrt{d} \in S^{\times}$, a, b > 0 such that b is minimal, then $a + b\sqrt{d}$ is the fundamental unit in S.

 - If $S = \mathbb{Z}[\frac{1+\sqrt{d}}{2}]$ (so $d \equiv 1 \pmod{4}$), then $\frac{1+\sqrt{5}}{2}$ is the fundamental unit in \mathcal{O}_5 . If d > 5 and $\frac{s+t\sqrt{d}}{2} \in \mathcal{O}_d^{\times}$ with s,t>0 such that t is minimal, then $\frac{s+t\sqrt{d}}{2}$ is the fundamental unit in \mathcal{O}_d .
- Remark: both $u = \frac{1+\sqrt{5}}{2}$ and $u^2 = \frac{3+\sqrt{5}}{2}$ have t minimal (equal to 1), which is why a separate case is needed for d = 5.
- Example:
 - $1+\sqrt{2}$ is fundamental unit in $\mathbb{Z}[\sqrt{2}]=\mathcal{O}_2$, since $N_K\left(1+\sqrt{2}\right)=-1$ so is a unit, and here b = 1, so is minimal (as b > 0).
 - $2+\sqrt{5}$ is the fundamental unit in $\mathbb{Z}[\sqrt{5}]$ (since b=1 is minimal) but is not the fundamental unit in \mathcal{O}_5 .
- Example: find fundamental unit in \mathcal{O}_7 . $7 \not\equiv 1 \pmod{4}$ so $\mathcal{O}_7 = \mathbb{Z}[\sqrt{7}]$. $a + b\sqrt{7}$ is a unit iff $a^2 - 7b^2 = \pm 1$. Also, by the above theorem, it is the fundamental unit if a, b > 0 and b is minimal. We use trial and error: for each b = 1, 2, ..., check whether $7b^2 \pm 1$ is a square

b	$7b^2 - 1$	$7b^2 + 1$	a^2
1	6	8	
2	27	29	_
3	62	64	$64 = 8^2$

So the unit with minimal b such that a, b > 0 is $8 + 3\sqrt{7}$, so is the fundamental unit.

4.3. Pell's equation and norm equations

- Definition: Pell's equation is $x^2 dy^2 = 1$ for nonsquare d, where solutions are $x,y\in\mathbb{Z}$. Since LHS is norm of $x+y\sqrt{d}$, solutions are given by $x+y\sqrt{d}\in\mathbb{Z}[\sqrt{d}]$ with norm 1.
- Example: consider $x^2 2y^2 = \pm 1$. Fundamental unit in $\mathbb{Z}[\sqrt{2}]$ is $u = 1 + \sqrt{2}$, with norm -1. So if $x + y\sqrt{2} \in \mathbb{Z}[\sqrt{2}]$ is such that $N_{\mathbb{Z}(\sqrt{2})}(x + y\sqrt{2}) = 1$, then $x+y\sqrt{2}$ is an even power of u. Thus elements of norm ± 1 are

$$\pm u^{2n} \; ({\rm RHS} = 1), \quad \pm u^{2n+1} \; ({\rm RHS} = -1)$$

To extract solutions x, y, note that if $x + y\sqrt{2} = \pm u^r$, then $x - y\sqrt{2} = \pm \overline{u}^r$, hence

8

$$x = \pm \frac{u^r + \overline{u}^r}{2}, \quad y = \pm \frac{u^r - \overline{u}^r}{2\sqrt{2}}$$

Solutions when RHS = 1 are given by even r, solutions when RHS = -1 are given

• Example: consider $x^2 - 75y^2 = 1$. $75 = 3 \cdot 5^2$ is not square-free, so rewrite as

$$x^2 - 3z^2 = 1$$

where z = 5y. Fundamental unit in $\mathbb{Z}[\sqrt{3}]$ is $u = 2 + \sqrt{3}$ of norm 1 so solutions are

$$x = \pm \frac{u^n + \overline{u}^n}{2}, \quad z = \pm \frac{u^n - \overline{u}^n}{2\sqrt{3}}, \quad n \in \mathbb{Z}$$

To get solution for (x, y), we need $5 \mid z$ (which doesn't always hold). Note that

$$u^2 = 7 + 4\sqrt{3} \notin \mathbb{Z}[\sqrt{75}] = \mathbb{Z}[5\sqrt{3}], \quad u^3 = 26 + 3\sqrt{75} \in \mathbb{Z}[\sqrt{75}]$$

Thus when n=2, (x,z) is not solution, but is when n=3, and hence when n=3kfor $k \in \mathbb{Z}$:

$$x = \pm \frac{u^{3k} + \overline{u}^{3k}}{2}, \quad y = \pm \frac{u^{3k} - \overline{u}^{3k}}{5 \cdot 2\sqrt{3}}, \quad k \in \mathbb{Z}$$

 u^{3k+1} and u^{3k+2} never give solutions, since if $u^{3k+1} \in \mathbb{Z}[\sqrt{75}]$, then $u \in \mathbb{Z}[\sqrt{75}]$ (since $u^{-3k} \in \mathbb{Z}[\sqrt{75}]$). Similarly, if $u^{3k+2} \in \mathbb{Z}[\sqrt{75}]$, then $u^2 \in \mathbb{Z}[\sqrt{75}]$: contradiction. Note $\mathbb{Z}[\sqrt{75}] \subset \mathbb{Z}[\sqrt{3}]$ and any unit in $\mathbb{Z}[\sqrt{75}]$ is unit in $\mathbb{Z}[\sqrt{3}]$, so is $\pm u^r$ for some $r \in \mathbb{Z}$. So by taking powers of u, eventually we find the fundamental unit in $\mathbb{Z}[\sqrt{75}]$ (as it will be smallest unit > 1 assuming we increment powers from 1).

5. Discriminants and integral bases

5.1. Discriminant of an *n*-tuple

• **Definition**: let K number field of degree n. **Discriminant** of $\gamma = (\gamma_1, ..., \gamma_n) \in K^n$ is

$$\Delta_K(\gamma)\coloneqq \det(Q(\gamma))$$

where $Q(\gamma)=(\operatorname{tr}_K(\gamma_i\gamma_j))_{1\leq i,j\leq n}\in M_n(\mathbb{Q}).$ • Example: let $K=\mathbb{Q}(\sqrt{d}),\, d\neq 1$ squarefree.

$$\gamma = (1, \sqrt{d}) \Longrightarrow Q(\gamma) = \begin{bmatrix} 2 & 0 \\ 0 & 2d \end{bmatrix} \Longrightarrow \Delta_K(\gamma) = 4d$$

$$\gamma = (1, \frac{1+\sqrt{d}}{2}) \Longrightarrow Q(\gamma) = \begin{bmatrix} 2 & 1 \\ 1 & \frac{1+d}{2} \end{bmatrix} \Longrightarrow \Delta_K(\gamma) = d$$

- Proposition:
 - $\Delta_K(\gamma) \in \mathbb{Q}$ and if every $\gamma_i \in \mathcal{O}_K$, then $\Delta_K(\gamma) \in \mathbb{Z}$.

- Let $M \in M_n(\mathbb{Q})$, then $\Delta_K(M\gamma) = \det(M)^2 \Delta_K(\gamma)$.
- $\Delta_K(\gamma)$ is invariant under permutations of $\gamma_1, ..., \gamma_n$.
- Lemma: let $\theta_1,...,\theta_n \in \mathbb{C}$, let

$$D = \begin{bmatrix} 1 & \theta_1 & \dots & \theta_1^{n-1} \\ \vdots & \vdots & \ddots & \vdots \\ 1 & \theta_n & \dots & \theta_n^{n-1} \end{bmatrix}$$

then

$$\det(D) = (-1)^{\binom{n}{2}} \prod_{1 \leq r < s \leq n} (\theta_r - \theta_s)$$

Theorem: let $K = \mathbb{Q}(\theta)$ be number field. Let $\theta_1, ..., \theta_n$ be roots of $p_{\theta}(x)$, let $\gamma = (1, ..., \theta^{n-1})$. Then

$$\Delta_K(\gamma) = \prod_{1 \leq i < j \leq n} (\theta_i - \theta_j)^2 = (-1)^{\binom{n}{2}} \prod_{i=1}^n p_\theta'(\theta_i) = (-1)^{\binom{n}{2}} N_K(p_\theta'(\theta))$$

- Example:
 - Let $K = \mathbb{Q}(\sqrt{d})$, d square-free, $\theta = \frac{1+\sqrt{d}}{2}$, then

$$\Delta_K((1,\theta)) = \left(\frac{1+\sqrt{d}}{2} - \frac{1-\sqrt{d}}{2}\right)^2 = d$$

• Let $\theta = \sqrt{d}$, so $p_{\theta}(x) = x^2 - d$, $p'_{\theta}(x) = 2x$, so

$$\Delta_K(1,\theta) = (-1)^{\binom{2}{2}} N_K(2\theta) = -4N_k(\theta) = 4d$$

• Let $\theta = \sqrt[d]{3}$, so $p_{\theta}(x) = x^3 - d$, $p'_{\theta}(x) = 3x^2$ so

$$\Delta_K(1,\theta,\theta^2) = (-1)^{\binom{3}{2}} N_K(3\theta^2) = -27d^2$$

• Let θ be root of $p_{\theta}(x) = x^3 - x + 2$, so $p'_{\theta}(x) = 3x^2 - 1$.

$$\Delta_K\big(1,\theta,\theta^2\big)=(-1)^{\binom{3}{2}}N_K\big(3\theta^2-1\big)$$

Now $\theta^3 = \theta - 2$ so

$$N_K\big(3\theta^2-1\big) = \frac{N_K(2)N_K(\theta-3)}{N_K(\theta)} = \frac{8}{2}N_K(3-\theta) = 4(3-\theta_1)(3-\theta_2)(3-\theta_3) = 4p_\theta(3) = 104$$

so $\Delta_K(1,\theta,\theta^2) = -104$. Note: in general, this method doesn't work, and generally we have to compute matrix T_{θ} and $\det(f(T_{\theta}))$. As a generalisation,

$$N_{\mathbb{O}(\theta)}(a-b\theta)=b^np_{\theta}(a/b)$$

- Lemma:
 - Roots $\theta_1, ..., \theta_n$ of $p_{\theta}(x)$ are distinct.

 - $\begin{array}{ll} \bullet & \forall f \in \mathbb{Q}[x], \operatorname{tr}_K(f(\theta)) = \sum_{i=1}^n f(\theta_i). \\ \bullet & \forall f \in \mathbb{Q}[x], N_K(f(\theta)) = \prod_{i=1}^n f(\theta_i). \end{array}$
- **Proposition**: let $K = \mathbb{Q}(\theta)$ number field. Then $\Delta_K(\gamma) \neq 0$ iff γ is \mathbb{Q} -basis of K.

5.2. Full lattices and integral bases

- **Definition**: let A subgroup of Q-vector space V. A is **full lattice** in V if there are $\gamma_1, ..., \gamma_n \in V$ such that
 - $\{\gamma_1, ..., \gamma_n\}$ is basis for V.
 - $A = \{a_1\gamma_i + \dots + a_n\gamma_n : a_i \in \mathbb{Z}\}$ (i.e. $\gamma_1, \dots, \gamma_n$ generate A as a group). Note a_1, \dots, a_n are uniquely determined for each $a \in A$.

 $\{\gamma_1,...,\gamma_n\}$ is **generating basis** for A.

- Example: let $K = \mathbb{Q}(\theta)$, $\theta \in \mathcal{O}_K$, $[K : \mathbb{Q}] = n$, then $\mathbb{Z}[\theta]$ has generating basis $\{1, ..., \theta^{n-1}\}$ and is full lattice in K.
- Example: \mathbb{Z} , $\mathbb{Z}[\sqrt{2}/2]$ are not full lattices in $\mathbb{Q}(\sqrt{2})$.
- **Proposition**: let K number field. Every non-zero ideal $I \subseteq \mathcal{O}_K$ is full lattice in K.
- **Definition**: generating basis for \mathcal{O}_K is **integral basis** for K.
- **Example**: let $K = \mathbb{Q}(\sqrt{d})$, then an integral basis for K is $\{1, \sqrt{d}\}$ if $d \not\equiv 1 \mod 4$, $\{1, (1+\sqrt{d})/2\}$ if $d \equiv 1 \mod 4$.
- **Theorem**: if V is \mathbb{Q} -vector space, $\dim(V) = n$, and $B \subset A \subset V$, A and B full lattices, $\{\beta_1, ..., \beta_n\}$ is generating basis for B, $\{\alpha_1, ..., \alpha_n\}$ is generating basis for A, where $\beta = M\alpha$, $M \in M_n(\mathbb{Z})$, then
 - $|A/B| = |\det(M)|$ (in particular, A/B is finite)
 - If V=K is number field, these satisfy **index-discriminant formula**: $\Delta_K(B)=|A/B|^2\Delta_K(A).$

(Note M exists since α is generating basis for A so spans B over \mathbb{Z}).

- Lemma: if $A \subset K$ is full lattice and $\{\gamma_1,...,\gamma_n\}$, $\{\delta_1,...,\delta_n\}$ are generating bases for A, then $\Delta_K(\gamma_1,...,\gamma_n) = \Delta_K(\delta_1,...,\delta_n)$. We define discriminant of A to be $\Delta_K(A) = \Delta_K(\gamma_1,...,\gamma_n)$ for any generating basis $\{\gamma_1,...,\gamma_n\}$.
- **Definition**: **disciminant** of number field K is

$$\Delta_K = \Delta_K(\mathcal{O}_K) = \Delta_K(\gamma_1,...,\gamma_n)$$

for any integral basis $\{\gamma_1,...,\gamma_n\}$.

5.3. When is $R = \mathbb{Z}[\theta]$?

- **Proposition**: if $S \subseteq \mathcal{O}_K$ is full lattice in $K = \mathbb{Q}(\theta)$, $\{\gamma_1, ..., \gamma_n\}$ is generating basis for S, and p prime, $p \mid |\mathcal{O}_K/S|$, then
 - $\bullet \quad p^2 \mid \Delta_K(S)$
 - There exists $\alpha=m_1\gamma_1+\cdots+m_n\gamma_n\in S,\,m_i\in\mathbb{Z},\,$ such that $\alpha/p\in\mathcal{O}_K-S$ and

$$\begin{cases} 0 \leq |m_i| < p/2 \text{ if } p \text{ is odd} \\ m_i \in \{0,1\} & \text{if } p = 2 \end{cases}$$

• Example: if $K = \mathbb{Q}(\sqrt{d})$,

$$\Delta_K = \begin{cases} 4d \text{ if } d \not\equiv 1 \bmod 4\\ d \text{ if } d \equiv 1 \bmod 4 \end{cases}$$

- Example: let θ be root of $x^3 + 4x + 1$, $K = \mathbb{Q}(\theta)$. We have $\mathbb{Z}[\theta] \subseteq \mathcal{O}_K$ and $\Delta_K(\mathbb{Z}[\theta]) = \Delta_K(1, \theta, \theta^2) = 281 = |\mathcal{O}_K/\mathbb{Z}[\theta]|^2 \Delta_K(\mathcal{O}_K)$. As 281 is squarefree, $|\mathcal{O}_K/\mathbb{Z}[\theta]| = 1$ so $\mathcal{O}_K = \mathbb{Z}[\theta]$.
- Example: let $K = \mathbb{Q}(\theta)$, $\theta = \sqrt[3]{5}$. let $R = \mathcal{O}_K$, $S = \mathbb{Z}[\theta]$. $\Delta_K(S) = -3^3 \cdot 5^2$. If p prime and $p \mid |R/S|$, then $p \in \{3, 5\}$ and there is $\alpha = a + b\theta + c\theta^2$ such that $\alpha/p \in R S$, |a|, |b|, |c| < p/2. Note $\alpha \neq 0$, as otherwise $\alpha \in S$.
 - If $5 \mid |R/S|$, then $|a|, |b|, |c| \in \{0, 1, 2\}$. Then $\operatorname{tr}_{K/\mathbb{Q}}(\alpha/5) = 3a/5 \in \mathbb{Z}$ so $5 \mid a$ so a = 0. $\theta \alpha = c + (b\theta^2)/5 \in \mathcal{O}_K$ so $(b\theta^2)/5 \in \mathcal{O}_K$ so

$$N_K\big((b\theta^2)/5\big) = \frac{N_K(b)N_K(\theta)^2}{N_K(5)} = \frac{b^3}{5} \in \mathbb{Z}$$

so $5 \mid b$, so b = 0. Finally,

$$N_K\left(\frac{\alpha}{5}\right) = N_K\left(\frac{c\theta^2}{5}\right) = \frac{c^3(-5)^2}{5^3} = \frac{c^3}{5} \in \mathbb{Z} \Longrightarrow c = 0$$

Contradiction.

• If $3 \mid |R/S|$, then $|a|, |b|, |c| \in \{0, 1\}$ and can assume $a \ge 0$ (by possibly multiplying by -1). Then

$$N_K\left(\frac{a+b\theta+c\theta^2}{3}\right) \in \mathbb{Z} \Longrightarrow a^3+5b^3+25c^3-15abc \equiv 0 \pmod{3^3}$$

If a=0, then $5b^3+25c^3\equiv 2b+c\equiv 0 \pmod 3$ (as $b,c\in\{0,1,-1\}$), so if b=0, then $c\equiv 0 \pmod 3 \implies c=0$: contradiction. So b=1 (by possibly multiplying by -1) hence c=1. But then

$$N_K(\alpha/3) = N_K\!\left(\frac{\theta + \theta^2}{3}\right) = \frac{N_K(\theta)N_K(1+\theta)}{3^3} = \frac{5\cdot 6}{27} \not\in \mathbb{Z}$$

Contradiction. If a = 1, then

$$1 + 5b^3 + 25c^3 \equiv 1 + 2b + c \equiv 0 \pmod{3}$$

which also leads to a contradiction.

• So $5 \nmid |R/S|$, $3 \nmid |R/S|$, so |R/S| = 1, so $\mathbb{Z}[\theta] = \mathcal{O}_K$.

6. Unique factorisation of ideals

• **Definition**: **product** of ideals $I, J \subseteq R$ is

$$IJ\coloneqq \left\{\sum_{i=1}^k x_iy_i: k\in\mathbb{N}, x_i\in I, y_i\in J\right\}$$

If $I = \langle a_1, ..., a_m \rangle$, $J = (b_1, ..., b_n)$ then

$$IJ = \langle a_i b_j \mid i \in [m], j \in [n] \rangle$$

- **Definition**: I divides $J, I \mid J$, if there is ideal K such that that IK = J.
- Note: to divide is to contain: $I \mid J \Longrightarrow J \subseteq I$.
- **Example**: let $R = \mathbb{Z}[\sqrt{-6}], I = (5, 1 + 3\sqrt{-6}), J = (5, 1 3\sqrt{-6}), \text{ then}$

$$IJ=\langle 25,5(1+3\sqrt{-6}),5(1-3\sqrt{-6}),55\rangle\subseteq\langle 5\rangle$$

But also $5 = 55 - 2 \cdot 25 \in I$, $\langle 5 \rangle \subseteq IJ$, so $IJ = \langle 5 \rangle$.

• Lemma: let I, J ideals, P prime ideal. Then

$$IJ \subseteq P \iff (I \subseteq P \lor J \subseteq P)$$

• Example: $\langle 5, 1+3\sqrt{-6} \rangle \subset \mathbb{Z}[\sqrt{-6}]$ is prime: define $\varphi : \mathbb{Z}[\sqrt{-6}] \to \mathbb{F}_5$, $\varphi(a+b\sqrt{-6}) = a-2b$. φ is surjective homomorphism. Also, $5, 1+3\sqrt{-6} \in \ker(\varphi)$, and

$$a + b\sqrt{-6} \in \ker(\varphi) \Longrightarrow b \equiv 3a \mod 5$$

$$\Longrightarrow (a + b\sqrt{-6}) - a(1 + 3\sqrt{-6}) = (b - 3a)\sqrt{-6} \in \langle 5 \rangle$$

so $\ker(\varphi) = (5, 1 + 3\sqrt{-6})$. So by first isomorphism theorem, $R/\langle 5, 1 + \sqrt{-6} \rangle \cong \mathbb{F}_5$ which is field, so $\langle 5, 3 + \sqrt{-6} \rangle$ is maximal, so prime.

• **Definition**: let K number field, $R = \mathcal{O}_K$. **Fractional ideal** of R is subset of K of the form

$$\lambda I = \{\lambda x : x \in I\}$$

where $\langle 0 \rangle \neq I \subseteq R$ and $\lambda \in K^{\times}$. If I = R, λI is **principal fractional ideal**. Set of fractional ideals in R is denoted $\mathcal{I}(R)$, set of principal fractional ideals is dented $\mathcal{P}(R)$.

- Example:
 - $\frac{n}{m}\mathbb{Z}$ is fractional ideal in \mathbb{Q} for all $m, n \in \mathbb{Z} \{0\}$.
 - Every non-zero ideal is fractional ideal (take $\lambda = 1$).
 - If λI is fractional ideal, then $\lambda^{-1}\lambda I = I$ is ideal.
- **Definition**: a fractional ideal A is **invertible** if there is fractional ideal B such that $AB = \mathcal{O}_K$. B is the **inverse** of A. The invertible fractional ideals form a group.
- Example: in $\mathbb{Z}[\sqrt{-6}] = \mathcal{O}_K$, $\langle 5, 1 + 3\sqrt{-6} \rangle \langle 5, 1 3\sqrt{-6} \rangle = \langle 5 \rangle$ so

$$\langle 5, 1 + 3\sqrt{-6} \rangle \cdot \frac{1}{5} \langle 5, 1 - 3\sqrt{-6} \rangle = \mathcal{O}_K$$

so inverse of $\langle 5, 1 + 3\sqrt{-6} \rangle$ is $\frac{1}{5}\langle 5, 1 - 3\sqrt{-6} \rangle$.

• **Definition**: the **class group** of K is the quotient group F/P where F is abelian group of fractional ideals of K, P is subgroup of principal fractional ideals of K.
